This Event is brought to you for free and open access by the Dept. of Mathematics and Applied Mathematics at VCU Scholars Compass. It has been accepted for inclusion in Biology and Medicine Through Mathematics Conference by an authorized administrator of VCU Scholars Compass. For more information, please contact libcompass@vcu.edu.

Experimental studies have shown that size and infectious-stage of viral inoculum influence disease outcomes in rhesus macaques infected with simian immunodeficiency virus. The possible contribution to disease outcome of antibody developed after transmission and/or present in the inoculum in free or bound form is not understood. In this study, we develop a mathematical model of virus-antibody immune complexes formation and use it to predict their role in transmission and protection. The model exhibits bi-stable dynamics between cleared and persistent states. We fitted it to temporal virus data and estimated parameter values for free virus infectivity rate and antibody's carrying capacity for which the model transitions between virus clearance and persistence when the initial conditions (in particular the immune complexes to free virus ratio) vary. We used these results to make predictions on the minimum virus load in the inoculum leading to persistent infection in the presence and absence of protective antibody responses.
