(Received 6 February 2013; accepted 21 March 2013; published online 22 April 2013)

The electronic and geometrical structures of the  $M_{12}$  and  $M_{13}$  clusters where  $M =$  Sc, Ti, V, Cr, Mn, Fe, Co, Ni, Cu, and Zn along with their singly negatively and positively charged ions are studied using all-electron density functional theory within the generalized gradient approximation. The geometries corresponding to the lowest total energy states of singly and negatively charged ions of  $V_{13}$ ,  $Mn_{12}$ ,  $Co_{12}$ ,  $Ni_{13}$ ,  $Cu_{13}$ ,  $Zn_{12}$ , and  $Zn_{13}$  are found to be different from the geometries of the corresponding neutral parents. The computed ionization energies of the neutrals, vertical electron detachment energies from the anions, and energies required to remove a single atom from the *M*<sup>13</sup> and  $M_{13}$ <sup>+</sup> clusters are in good agreement with experiment. The change in a total spin magnetic moment of the cation or anion with respect to a total spin magnetic moment of the corresponding neutral is consistent with the one-electron model in most cases, i.e., they differ by  $\pm 1.0 \mu_B$ . Exceptions are found only for Sc12−, Ti12+, Mn12−, Mn12+, Fe12−, Fe13+, and Co12+. *© 2013 American Institute of Physics*. #### **I. INTRODUCTION**

Transition metal clusters  $M_n$  possess many exceptional properties<sup>[1](#page-11-0)</sup> and have been the subject of numerous studies by experimental and theoretical groups. Due to their unfilled *d*shells, transition metal clusters carry magnetic moments and can couple magnetically even though they are nonmagnetic in the bulk. In addition, many isomers with different spin magnetic moments are energetically nearly degenerate and this poses great challenges for theory to identify the true ground state of a transition metal cluster. Among these clusters, the  $nd$ -metal  $M_{13}$  species have received the most attention because of at least two reasons. First, the smallest icosahedral and cuboctahedral structures are composed of 13 atoms. Second, many transition metal clusters exhibit magic numbers at  $n = 13$  in their time-of-flight mass spectra.<sup>[2](#page-11-1)</sup> Several recent theoretical papers have recently been devoted to the computational study of clusters composed of 13 atoms in the whole range of the  $3d$ -,  $4d$ -, and  $5d$ -metal series.<sup>3[–8](#page-11-3)</sup> All these computations were performed using density functional theory (DFT) and effective core potentials with cores of different size.

While majority of the previous theoretical studies on *M*<sup>13</sup> have been performed on the neutral species, experimental studies using mass-spectrometry and laser electron photodetachment techniques are performed on positively and negatively charged ions. To assess the accuracy of DFT methods, it is, therefore, necessary to study not only the neutral but also positively and negatively charged clusters. Our objective in this paper is to bridge this gap by carrying out a systematic and comprehensive study of the neutral and positively and negatively charged transition metal clusters. We have focused our study on the 13-atom clusters as we can not only compare our neutral structures with previous calculations, but also compare our results with experimental values of the vertical ionization energies (VIEs) of the neutral, vertical electron detachment energies from the anion, dissociation energies, and magnetic moments of the neutral and cationic species. This is achieved by performing all-electron DFT computations with generalized gradient approximation (GGA) on the  $M_{13}$ ,  $M_{13}^-$ , and  $M_{13}$ <sup>+</sup> series with *M* from Sc to Zn. In order to obtain binding energies of atoms in the  $M_{13}$  and  $M_{13}$ <sup>+</sup> series, many of which were measured experimentally, we also considered the  $M_{12}$ ,  $M_{12}^-$ , and  $M_{12}^+$  series with *M* from Sc to Zn. These optimizations will provide additional theoretical values that can be compared with experimental data on the electron affinities and ionization energies.

The paper is organized as follows. First, we consider results of optimizations for each neutral  $M_{12}$  and  $M_{13}$  pair and their singly charged positive and negative ions. Second, we compute ionization energies and electron affinities for the lowest total energy states and compare these with experiment. Third, we compare our computed total spin magnetic moments with the experimental values available for Sc, Mn, Fe, Co, and Ni clusters. Finally, we compare our computed energies required to remove a single atom from  $M_{13}$  and  $M_{13}$ <sup>+</sup> with the corresponding experimental values, as well as with the bulk cohesive energies and binding energies of the  $M_2$  dimers.

Our calculations are performed using DFT-GGA. The exchange-correlation functional is based on the Becke's

exchange<sup>9</sup> and Perdew-Wang correlation,<sup>[10](#page-11-5)</sup> known as the BPW91 functional. The choice of this functional among many others is based on our previous assessment of this functional for 3*d*-metal oxides,  $1\overline{1}$ [–13](#page-11-7) and the BPW91 stability in harmonic frequency calculations of closely spaced states of iron clusters.<sup>[14](#page-11-8)</sup> The BPW91 functional is found to produce results which are quite close to those obtained using the coupled-cluster method with singles and doubles and non-iterative inclusion of triples  $[CCSD(T)]^{15}$  $[CCSD(T)]^{15}$  $[CCSD(T)]^{15}$  for  $(TiO_2)_n$ clusters,  $^{16}$  $^{16}$  $^{16}$  (CrO<sub>3</sub>)<sub>n</sub> clusters,  $^{17,18}$  $^{17,18}$  $^{17,18}$  and FeO<sub>2</sub>.<sup>[19](#page-11-13)</sup> Good agreement between the BPW91 results and experimental data was also obtained for  $Cr_3O_8^{-}.^{20}$  $Cr_3O_8^{-}.^{20}$  $Cr_3O_8^{-}.^{20}$  The quality of new exchangecorrelation functionals has been intensively tested using different databases $^{21}$  $^{21}$  $^{21}$  and the PW91 functional was found to have a good performance with respect to the best new functionals.<sup>[22](#page-11-16)</sup> In particular, the PW91 method was found to have mean unsigned errors for transition metal atomization energies comparable to some of the most recent local and hybrid functionals.

The atomic orbitals are represented by the GAUSSIAN 6- 311+*G*\* basis set [(15*s*11*p*6*d*1*f*/10*s*7*p*4*d*1*f*) [23,](#page-11-17) [24](#page-11-18) of the triple*ζ* quality. Trial geometries were optimized without imposing symmetry constraints using the keyword NOSYMM in the GAUSSIAN  $09 \text{ code.}^{25}$  For each neutral cluster, we tested a number of geometrical structures available in the literature as well as those generated from the layered structures  $N_1 - N_2$  $\ldots$  *N*<sub>k</sub>, where *N*<sub>i</sub> is number of atoms in the *i*th layer, with interatomic distances typical for a given atom. Pre-optimizations of states with trial structures were performed using a smaller 6-311*G*\* basis set. In optimizations of the ions, we started with the geometrical structures found for the neutral lowest total energy state as well as the energetically closest isomers.

For a given geometrical structure, all possible spin multiplicities were tried in order to determine the total spin of the lowest total energy state. The convergence threshold for total energy was set to  $10^{-8}$  eV and the force threshold was set to  $10^{-3}$  eV/Å. Each geometry optimization was followed by harmonic frequency computations in order to confirm the stationary character of the state obtained. If geometry optimization led to a transition state, further optimizations following the imaginary frequency modes were performed until all imaginary frequencies are eliminated. Local spin magnetic moments on atoms which are identified with the excess spin densities on atoms are obtained using the Natural Atomic Orbital  $(NAO)^{26}$  $(NAO)^{26}$  $(NAO)^{26}$  population analysis.

# **III. RESULTS AND DISCUSSION**

## **A. Geometrical structures**

#### **1. Sc<sup>13</sup> and Sc<sup>12</sup>**

Following the Stern-Gerlach measurements<sup>[27](#page-11-21)</sup> of a total magnetic moment of neutral Sc*<sup>n</sup>* clusters, several theoretical studies $28-33$  $28-33$  using both all-electron and effective core potential (ECP) methods were performed with the aim to reproduce the experimental values. All theoretical studies including the present work found the lowest total energy state of  $Sc_{13}$  to possess nearly icosahedral geometry (see Fig. [1\)](#page-2-0) and a total spin magnetic moment of 19  $\mu$ <sub>B</sub> which is very far from

<span id="page-2-0"></span>

FIG. 1. Geometrical structure and local spin magnetic moments in the lowest total energy states of the neutral and charged  $Sc_n$  and  $Ti_n$  clusters,  $n = 12$ and 13. Bond lengths are in Angstroms, magnetic moments are in Bohr magnetons, and *M* is the spin multiplicity  $2S + 1$ .

the experimental value of  $6.0 \pm 0.2 \mu_{\rm B}$ . According to the results of our optimizations performed without imposing symmetry constraints, the closest in total energy state with a total spin magnetic moment of 17  $\mu$ B is higher in total energy by 0.27 eV. The states with total spin magnetic moments of 5  $\mu$ <sub>B</sub> and 7  $\mu$ <sub>B</sub> which are close to the value obtained in the experiment are higher in total energy by 1.71 eV and 1.62 eV, respectively.

According to the results of our NAO analysis, the valence population at the central Sc atom is  $4s^{0.43}3d^{4.67}4p^{1.55}4d^{0.21}$ and corresponds to the AO occupation by 6.86 electrons. That is, the central atom carries a negative charge of −3.86*e*. All surface atoms possess the valence population of  $4s^{0.41}3d^{1.83}4p^{0.46}$ , composed of the  $\alpha$ - $4s^{0.26}3d^{1.57}4p^{0.29}$  and  $\beta$ -4*s*<sup>0.15</sup>3*d*<sup>0.26</sup>4*p*<sup>0.17</sup> constituents, which corresponds to the charge of +0.3*e* per atom. Note, that there is no exact charge balance because of neglected small contributions from AOs with higher quantum numbers.

Reoptimizations of this  $Sc_{13}$  state obtained without symmetry constraints with imposing  $I_h$  symmetry constrains resolved by symmetry the valence molecular orbitals

(MO) but left unresolved by symmetry MOs composed of the core AOs. If  $I_h$  symmetry is reduced to  $T_h$ , then one obtains all symmetry resolved MOs corresponding to the  $^{20}A_u$  state. This state is degenerate in total energy with the state obtained without symmetry constraints whose NAO populations are given above. However, a drastic change in NAO population is observed in the  $^{20}A_u$  state. The effective electronic configuration of the central atom in this state is  $4s^{0.69}3d^{5.47}4p^{0.05}4d^{0.14}$ , which corresponds to a charge of  $-3.35e$ . All other atoms possess the  $4s^{0.72}3d^{1.92}4p^{0.03}4d^{0.08}$ effective electronic configurations corresponding to a charge of  $+0.24e$ . That is, there is almost no  $4s \rightarrow 4p$  promotion in the  $^{20}A_u$  state. Apparently, there is a strong competition between 4*s* promotion to vacant 3*d* and 4*p* AOs.

The lowest total energy state of  $Sc_{12}$  possesses a slightly distorted icosahedral geometry with a total spin magnetic moment of 16  $\mu$ <sub>B</sub> and is nearly degenerate in total energy with the states whose total spin magnetic moments are  $14 \mu_B$  $(+0.05 \text{ eV})$ , 12  $\mu_B$  (+0.06 eV), and 6  $\mu_B$  (+0.10 eV). A state of  $Sc_{12}$  with a total spin magnetic moment of 2  $\mu_B$  possesses a cylindrical geometrical structure which is produced from that presented in Fig. [1](#page-2-0) by shifting the central and apex atoms to the centers of the cylinder planes formed by two fivemembered rings. We found that the lowest energy state with this geometry is the state with a total spin magnetic moment of 6  $\mu$ <sub>B</sub> which is higher in total energy by 0.15 eV than the lowest total energy state with a total spin magnetic moment of 16  $\mu$ <sub>B</sub>. The charge on the central Sc atom reduces to  $-3.14$  *e* and the 4*p* occupation of all atoms is nearly depleted.

Both detachment and attachment of an electron from/to  $Sc_{12}$  and  $Sc_{13}$  do result in minor changes in the geometrical structures of the neutrals. If one accepts a one-electron model where an electron detaches/attaches from/to a spin-up or spin-down occupied/virtual orbital without significant reconstruction of the rest of orbitals, then a total spin magnetic moment of a charged cluster would change from its neutral value by  $\pm 1.0 \mu_{\rm B}$ . This is the case for the  $\rm Sc_{12}-Sc_{12}^+$ ,  $\rm Sc_{13} Sc_{13}^-$ , and  $Sc_{13}-Sc_{13}^+$  pairs but not for the  $Sc_{12}-Sc_{12}^-$  pair, where the change is 5.0  $\mu$ <sub>B</sub>. The states of Sc<sub>12</sub><sup>−</sup> that do satisfy the one-electron rule are higher in total energy by  $+0.02$  eV (a total spin magnetic moment of 15  $\mu$ <sub>B</sub>) and +0.05 eV (a total spin magnetic moment of 17  $\mu$ B). It will be interesting to compare the magnetic moments of  $Sc_{12}^+$  and  $Sc_{13}^+$  with experiments when available.

# **2.**  $Ti_{13}$  and  $Ti_{12}$

Geometrical structures found for the lowest total energy states of the neutral and charged  $Ti<sub>12</sub>$  and  $Ti<sub>13</sub>$  clusters are displayed in Fig. [1.](#page-2-0) The geometrical structure of the lowest total state of neutral  $Ti<sub>13</sub>$  is found to be a slightly distorted icosahedron (ICO) in agreement with the previous assignments. $34-43$  $34-43$ Our value of 6  $\mu$ B for the total spin magnetic moment of Ti<sub>13</sub> is also in agreement with the result of a recent study.<sup>44</sup> The effective electron configuration of the central Ti atom in  $Ti<sub>13</sub>$ is  $4s^{0.40}3d^{4.41}4p^{1.38}4d^{0.19}$ , which means that the central atom carries a negative charge of −2.4*e*. The effective electron configurations of two apex atoms are  $4s^{0.35}3d^{2.99}4p^{0.36}4d^{0.02}$  and all other atoms have the  $4s^{0.39}3d^{3.06}4p^{0.40}4d^{0.02}$  configuration.

The geometrical structure of the lowest total energy state of  $Ti_{12}$  is formed from the  $Ti_{13}$  geometry by the removal of an apex atom in agreement with the results of previous studies. As is seen from Fig. [1,](#page-2-0) this removal causes serious changes in the local spin magnetic moments with respect to those in  $Ti<sub>13</sub>$ and the rupture of bonds in the bottom pentagon ring. Our value of a total spin magnetic moment is  $2 \mu_{\rm B}$ , which is the same as that obtained at the BLYP level by Medina *et al.*[44](#page-11-26)

The lowest total energy states of  $Ti_{13}^+$  and  $Ti_{13}^-$  possess strongly distorted icosahedral geometrical configurations with large variations in the local spin magnetic moment values. Total spin magnetic moments of Ti<sub>13</sub><sup>+</sup> and Ti<sub>13</sub><sup>-</sup> are 7  $\mu_B$ and  $5 \mu_B$ , respectively, which is in agreement with the results of a previous study.<sup>45</sup> Whereas the single-electron rule is valid for the electron attachment and detachment processes of  $Ti<sub>13</sub>$ , it is not so for  $Ti_{12}$  because its cation has a total spin magnetic moment of 9  $\mu$ <sub>B</sub>. In order to make sure that this is not an artifact of the basis set, we recomputed the cation states using the 6-311+*G*(3*df*) basis set (15*s*11*p*6*d*3*f*1*g*/10*s*7*p*4*d*3*f*1*g*). The results of optimizations with the  $6-311+G^*$  and  $6-$ 311+*G*(3*df*) basis sets for the states with total spin magnetic moments from 1  $\mu_B$  to 11  $\mu_B$  are presented in Fig. [2.](#page-3-0) As is seen, the "skirt" bonds are all broken in the states with total spin magnetic moments larger than  $3 \mu_B$  and the basis extension does not lead to the change in the order of total energies of the states. The state with a total spin magnetic moment of  $3 \mu_{\rm B}$ , which satisfies the one-electron rule, is higher in total energy by 0.01–0.02 eV.

<span id="page-3-0"></span>

FIG. 2. Geometrical structures of the  $Ti_{12}^+$  isomers corresponding to the lowest total energy states with the spin multiplicity from 2 to 12. Bond lengths are in Angstroms, magnetic moments are in Bohr magnetons, and *M* is for the spin multiplicity  $2S + 1$ . The values in parentheses are obtained using the 6-311+*G*(3*df*) basis set.

<span id="page-4-0"></span>

FIG. 3. Geometrical structure and local spin magnetic moments in the lowest total energy states of the neutral and charged  $V_n$  and  $Cr_n$  clusters,  $n = 12$  and 13. Bond lengths are in Angstroms, magnetic moments are in Bohr magnetons, and  $M = 2S + 1$ . In the Cr<sub>n</sub> series, the red and blue colors are used to mark atoms with the local spin-up and spin-down magnetic moments, respectively.

# **3.**  $V_{13}$  and  $V_{12}$

The geometrical structures of the lowest total energy states found for the neutral and charged  $V_{13}$  and  $V_{12}$  clusters are shown in Fig.  $3$ . The V<sub>13</sub> cluster has a doublet lowest total energy state with a strongly distorted  $I_h$  geometry in agreement with the previous studies. $46,47$  $46,47$  Our structure is open in the bottom where the bonds between the atoms are broken. However, the determination of the lowest total energy state is difficult because we found eight doublet and quartet states whose difference in total energy with respect to the lowest en-ergy state given in Fig. [3](#page-4-0) is less than 0.1 eV. Both  $V_{13}^+$  and  $V_{13}$ <sup>-</sup> possess the singlet lowest total energy states with distorted icosahedral geometrical configurations. All  $V_{12}$  species are found to possess the bell-shaped geometrical structures in their lowest total energy states. An icosahedral cage structure was previously found<sup>48</sup> for the lowest total energy doublet state of the  $V_{12}$ <sup>+</sup> cation. According to the results of our BPW91/6-311+G\* computations, the  $V_{12}$ <sup>+</sup> doublet state with such a cage structure is above the state whose geometrical structure is given in Fig. [3](#page-4-0) by only 0.007 eV. Reoptimizations at the BPW91/6-311+*G*(3*df*) level resulted in a larger total energy difference of +0.028 eV; therefore, we accept the structure in Fig. [3](#page-4-0) as corresponding to the lowest total energy state of  $V_{12}^+$ . No violation of the one-electron rule is found for either  $V_{12}$  or  $V_{13}$ .

# **4. Cr<sup>13</sup> and Cr<sup>12</sup>**

According to the results of previous computations,  $49,50$  $49,50$ the lowest total energy state of  $Cr_{13}$  is either a cubo-octahedral or an icosahedron type structure.<sup>[7](#page-11-33)</sup> The geometrical structure we found for the lowest total energy antiferromagnetic singlet state of  $Cr_{13}$  (see Fig. [3\)](#page-4-0) has a similar shape and the same arrangement of atoms carrying spin-up and spin-down magnetic moments as found previously in Ref. [7.](#page-11-33) One bond between the atoms possessing the spin-up magnetic moments is broken in the upper and bottom pentagons. Both attachment and detachment of an electron do not lead to the change in the geometrical structure of the neutral lowest total energy state.

The lowest total energy states of  $Cr_{12}$  and its ions possess the bell-type geometrical structures with a broken bond in the bottom pentagon (see Fig. [3\)](#page-4-0). The lowest total energy state of  $Cr_{12}$  possesses a total spin magnetic moment of 4  $\mu$ <sub>B</sub> whereas both the ions have the same total spin magnetic moment of  $3 \mu_B$  in accordance with the one-electron rule. The neutral singlet, triplet, and nonet states are higher in total energy by only 0.07 eV, 0.01 eV, and 0.02 eV, respectively. The doublet state of the  $Cr_{12}^-$  anion is only marginally higher in total energy by 0.01 eV than its quartet state, whereas the doublet state of the cation is higher in total energy by 0.09 eV than the cation quartet state. The sextet states of both anion and cation are higher than their quartet states by 0.14 eV and 0.40 eV, respectively.

#### **5. Mn<sup>13</sup> and Mn<sup>12</sup>**

The lowest total energy state of  $Mn<sub>13</sub>$  is an antiferromagnetic quartet and possesses a slightly distorted icosahedral ge-ometrical structure.<sup>[51](#page-11-34)[–55](#page-11-35)</sup> The Mn<sub>13</sub><sup>+</sup> and Mn<sub>13</sub><sup>-</sup> ions do possess similar geometrical structures (see Fig. [4\)](#page-5-0) as their neutral parent with total magnetic moments of 2  $\mu$ <sub>B</sub> and 4  $\mu$ <sub>B</sub>, respectively.<sup>[56,](#page-11-36) [57](#page-11-37)</sup> The NAO effective electronic configuration of the central Mn atom is  $3d^{7.53}4s^{0.97}4p^{0.15}$  and corresponds to the charge of  $+1.65e$ .

There is no agreement between our results and previous studies on a total spin magnetic moment of the  $Mn_{12}$ cluster. Whereas we obtained the same arrangement of local spin magnetic moments as obtained by Bobadova-Parvanova *et al.*,<sup>[58](#page-11-38)</sup> our total spin magnetic moment is smaller by 4  $\mu_B$ . Kabir *et al.*<sup>[59](#page-11-39)</sup> obtained a total spin magnetic moment of 16  $\mu_B$ for  $Mn_{12}$ , i.e., twice as large as our value. Because of various possible arrangements of spin-up and spin-down local spin magnetic moments,  $Mn<sub>12</sub>$  and its ions possess a plenty of states, many of which are close in total energy. We found dozens of states, which are within 0.1 eV in total energy from the lowest total energy state in both neutral and charged  $Mn_{12}$ clusters. Therefore, the assignment of the ground state for these clusters is challenging. The one-electron rule is valid for the  $n = 13$  series but not for the  $n = 12$  series.

<span id="page-5-0"></span>

FIG. 4. Geometrical structure and local spin magnetic moments in the lowest total energy states of the neutral and charged  $Mn_n$  and  $Fe_n$  clusters,  $n = 12$ and 13. Bond lengths are in Angstroms, magnetic moments are in Bohr magnetons, and  $M = 2S + 1$ . In the Mn<sub>n</sub> series, the red and blue colors are used to mark atoms with the local spin-up and spin-down magnetic moments, respectively.

#### **6. Fe<sup>13</sup> and Fe<sup>12</sup>**

The ground state geometries of the neutral and charged Fe12 and Fe13 clusters are displayed in the bottom panels of Fig. [4.](#page-5-0) The iron clusters possess the largest total spin magnetic moments in the Sc–Zn series although the largest local spin magnetic moments belong to the Mn clusters. The lowest total energy states of the  $Fe_{13}$  and  $Fe_{13}^-$  clusters possess Jahn-Teller distorted icosahedral geometries, <sup>[60](#page-11-40)[–69](#page-12-0)</sup> whereas the lowest total energy state of  $Fe_{13}^+$  has  $T_h$  symmetry.<sup>70</sup> Note that the neutral Fe<sub>13</sub> state possesses  $T_h$  symmetry at  $2S + 1 = 47$ whereas the lowest total energy state of  $Fe<sub>13</sub>$  has the spin multiplicity of 45. The lowest total energy states of  $Fe_{12}$  and its ions possess similar geometrical structures of an icosahedron with an apex atom removed. The one-electron rule is not valid for either Fe<sub>13</sub> or Fe<sub>12</sub>. An especially drastic change in the total spin magnetic moment is observed<sup>71</sup> for  $Fe_{13}^+$ , whose total spin magnetic moment is smaller than that of its neutral parent by 9  $\mu$ <sub>B</sub>. The results of our computations are in agreement with this finding. A detailed discussion on the structure and peculiarities of the neutral and singly charged iron clusters Fe<sub>n</sub>  $(n = 7-20)$  can be found in our recent paper.<sup>72</sup>

#### **7. Co<sup>13</sup> and Co<sup>12</sup>**

The geometry of the lowest total energy state of  $Co<sub>13</sub>$  obtained in a number of studies corresponds to a slightly dis-torted ICO<sup>[73–](#page-12-4)[79](#page-12-5)</sup> whereas other studies<sup>[80–](#page-12-6)[82](#page-12-7)</sup> predicted the Co<sub>13</sub> geometry to be a hexagonal bilayer (HBL). These studies have shown that the values of the local spin magnetic moments depend strongly on the geometrical structure found for the lowest total energy state as well as on the method and basis set used.<sup>[83](#page-12-8)</sup> Lv *et al.*<sup>[84](#page-12-9)</sup> performed all-electron DFT optimizations for two states of  $Co<sub>13</sub>$  possessing the ICO and HBL structures in the range of total spin magnetic moments from 13  $\mu_B$ to 33  $\mu$ B. They found the absolute minimum in total energy to correspond to a state with the HBL geometry and a total spin magnetic moment of 27  $\mu$ <sub>B</sub>. A state with an ICO geometry and a total spin magnetic moment of 31  $\mu$ <sub>B</sub> was found to correspond to a local minimum, which is below in total energy than the HBL state with this total spin magnetic moment. We found the HBL state of  $Co<sub>13</sub>$  to have the lowest total energy (Fig. [5\)](#page-5-1). Our search for the lowest total energy state of  $Co_{13}$  led to 7 states with the spin multiplicity of 28, including a state with a distorted ICO geometry as obtained

<span id="page-5-1"></span>

FIG. 5. Geometrical structure and local spin magnetic moments in the lowest total energy states of the neutral and charged  $Co<sub>n</sub>$  and  $Ni<sub>n</sub>$  clusters,  $n = 12$  and 13. Bond lengths are in Angstroms, magnetic moments are in Bohr magnetons, and  $M = 2S + 1$ .

by Datta *et al.*,<sup>[85](#page-12-10)</sup> whose total energies are placed between those of states with the HBL and ICO geometrical structures. The  $Co_{13}^-$  and  $Co_{13}^+$  ions also possess the HBL geometrical structures and obey the one-electron rule.

Both  $Co_{12}$  and  $Co_{12}^-$  possess geometrical configurations obtained from those of  $Co_{13}$  and  $Co_{13}^-$  via the removal of the top atom (see Fig. [5\)](#page-5-1). Extensive optimizations of  $Co_{12}^+$ yielded a state with an ICO geometry and a total spin magnetic moment of 21  $\mu$ B for the lowest total energy state. The geometrical configurations of  $Co_{12}^+$  states are also probed by removing the top or a bottom atom from the HBL configuration. This yielded a state with a total spin magnetic moment of 23  $\mu$ <sub>B</sub> which is only 0.03 eV higher in total energy than the lowest total energy state. The violation of the one-electron rule for the  $Co_{12}$ – $Co_{12}$ <sup>+</sup> pair can be related to the change in the geometrical topology.

# **8. Ni<sup>13</sup> and Ni<sup>12</sup> clusters**

An ICO structure and the magnetic moment of  $8 \mu_{\rm B}$  was found for the lowest total energy state of  $Ni<sub>13</sub>$  in the majority of previous studies.  $86-101$  $86-101$  However, two recent papers<sup>7, [102](#page-12-13)</sup> have obtained non-icosahedral structures for the lowest total energy state of  $Ni<sub>13</sub>$ , which correspond to structures **I** and **IV** shown in Fig. [6,](#page-6-0) respectively, and a total spin magnetic moment of 10  $\mu$ <sub>B</sub>. The computations were performed us-ing the Perdew-Burke-Ernzerhof (PBE) functional<sup>[103](#page-12-14)</sup> in both papers.

In order to gain insight into the dependence of the optimization results on the exchange-correlation functional and basis set used, we performed optimizations of four isomers presented in Fig. [6](#page-6-0) using the  $6-311+G^*$  and extended 6-311+*G*(3*df*) basis sets and four different methods, namely, the BPW91, PBE, TPSS,  $^{104}$  and M06-L $^{105}$  $^{105}$  $^{105}$  methods. The results of computations are presented in Table [I.](#page-6-1) As is seen, all four methods predict the icosahedral geometrical structure and 2*S*

<span id="page-6-0"></span>

FIG. 6. Geometrical structures of four isomers, which are candidates for the geometrical structures of the lowest total energy state of Ni13.

<span id="page-6-1"></span>TABLE I. Relative total energies of the  $Ni<sub>13</sub>$  isomers with the geometries **I**–**IV** displayed in Fig. [6.](#page-6-0) All values are in eV.

			Basis $6-311+G^*$

П	9	0.06	0.00	0.00	0.00

 $+ 1 = 9$  for the lowest total energy state of Ni<sub>13</sub> independent of the basis set used except for the BPW91 method. The electronic energy of the  $2S + 1 = 11$  state with geometrical configuration **I** is lower than that of the  $2S + 1 = 9$  state with geometrical configuration **II** by 0.027 eV at the BPW91/6-  $311+G*$  level. The addition of zero-point vibrational energies (ZPVE) to the electronic energies makes the latter state to be marginally lower in total energy. The basis extension leads to the decreasing differences in total energies obtained using the PBE, TPSS, and M06-L methods, whereas the  $2S + 1$ = 11 state with geometrical configuration **I** becomes the lowest total energy state at the BPW91/6-311+*G*(3*df*) level. Taking into account the trend toward decreasing the **I**–**II** difference in total energy when the basis set increases, we assign geometrical configuration **I** and  $2S + 1 = 11$  as corresponding to the lowest total energy state of  $Ni<sub>13</sub>$ .

An anion state with  $2S + 1 = 10$  and geometrical configuration **I** presented in Fig. [5](#page-5-1) is energetically lower by 0.09 eV than the state with  $2S + 1 = 8$  and geometrical configuration **II**. The latter state possesses the smallest total energy among the states with icosahedral geometries and different spin multiplicities. A state of the cation with  $2S + 1 = 10$  and an icosahedral geometrical structure (presented in Fig. [5\)](#page-5-1) is lower in total energy by  $0.04$  eV than the state with  $2S + 1 = 12$  and geometrical configuration **I**. It is worth noting that the cation states possessing geometrical configurations **I**–**IV** and total spin magnetic moments of 9  $\mu$ <sub>B</sub> and 11  $\mu$ <sub>B</sub>, are all within less than 0.1 eV in total energy.

All three clusters  $Ni<sub>12</sub>, Ni<sub>12</sub><sup>+</sup>, and Ni<sub>12</sub><sup>-</sup> possess similar$ geometrical configurations obtained from **I** by the removal of the front atom in the base (see Fig. [5\)](#page-5-1), and all of them possess isomers whose total energies are within 0.1 eV from the total energy of the corresponding lowest total energy states. No violation of the one-electron rule is observed for these nickel clusters.

# **9. Cu<sup>13</sup> and Cu<sup>12</sup>**

A number of different geometrical structures have previously been assigned for the lowest total energy states of the neutral Cu<sub>13</sub> and Cu<sub>12</sub> clusters.<sup>[7,](#page-11-33) [106](#page-12-17)[–114](#page-12-18)</sup> Somewhat

<span id="page-7-0"></span>

FIG. 7. Geometrical structure and local spin magnetic moments in the lowest total energy states of the neutral and charged  $Cu_n$  and  $Zn_n$  clusters,  $n = 12$ and 13. Bond lengths are in Angstroms, magnetic moments are in Bohr magnetons, and  $M = 2S + 1$ .

different geometrical structures were also obtained for the  $Cu_{13}$ <sup>+</sup> and  $Cu_{12}$ <sup>+</sup> cations<sup>[113,](#page-12-19)[115](#page-12-20)</sup> and the  $Cu_{13}$ <sup>-</sup> and  $Cu_{12}$ <sup>-</sup> anions.[113,](#page-12-19) [116,](#page-12-21) [117](#page-12-22) Our search for the geometrical structure of the lowest total energy state of  $Cu<sub>13</sub>$  resulted in the structure shown in Fig. [7](#page-7-0) which is similar to that found in the most recent papers cited above. The similar structures as found re-cently are obtained for the Cu<sub>13</sub> and Cu<sub>12</sub> ions (see Fig. [7\)](#page-7-0) in the present work as well. There is no violation of the oneelectron rule in the  $Cu_{13}$  and  $Cu_{12}$  series.

#### **10. Zn<sup>13</sup> and Zn<sup>12</sup>**

The geometrical configurations of the lowest total energy states of the neutral and charged  $Zn_{13}$  and  $Zn_{12}$  clusters are displayed in Fig. [7.](#page-7-0) Previously computed<sup>7, [118,](#page-12-23) [119](#page-12-24)</sup> geometrical structures for  $Zn_{13}$  and  $Zn_{12}$  are similar to those presented in the figure. Both attachment and detachment of an electron to/from either  $Zn_{13}$  or  $Zn_{12}$  result in substantial reconstructions of the neutral geometries except for  $Zn_{13}^-$ . As in the preceding case, there is no violation of the one-electron rule.

#### **B. Ionization energies and electron affinities**

In order to assess the quality of the present computations on the  $M_{12}$  and  $M_{13}$  neutrals and their ions, we begin with comparing our values of ionization energies with experiment. We computed the adiabatic ionization energy of a neutral according to the equation

$$
IEad(Mn) = Etotel(Mn+) + ZPVE(Mn+)
$$
  
– [E<sub>tot</sub><sup>el</sup>(M<sub>n</sub>) + ZPVE(M<sub>n</sub>)], (1)

where  $E_{\text{tot}}^{\text{el}}(M_n)$  and  $E_{\text{tot}}^{\text{el}}(M_n^+)$  are the total electronic energies of  $M_n$  and  $M_n^+$ , respectively, and ZPVE is the zero-point vibrational energy computed in the harmonic approximation.

The VIE of a neutral are computed at the geometry of the neutral lowest total energy state for two different electron detachment channels corresponding to the final cation states whose spin multiplicities differ from the spin multiplicity of the neutral parent by  $\pm 1$ . The corresponding formula for the VIE is given by the expression

$$
VIE_{\pm}(M_n) = E_{\text{tot}}^{\text{el}}(M_n^+, (2S+1) \pm 1) - E_{\text{tot}}^{\text{el}}(M_n, 2S+1). \tag{2}
$$

The computed values are compared with experiment in Table [II.](#page-8-0) Note that the experimental values are obtained from mass-spectrometry experiments and correspond to the vertical electron detachment processes. As is seen, the differences between the theoretical and experimental values do not exceed 0.2 eV when the experimental uncertainty bars are taken into account except for  $Mn_{12}$ .

Next, we compare the results of our computations for the  $M_{12}$ <sup>–</sup> and  $M_{13}$ <sup>–</sup> anions with experiment. The adiabatic energy of an electron attachment to a neutral corresponds to the adiabatic electron affinity (*EA*ad) of the neutral and is computed as

$$
EAad(Mn) = Etotel(Mn) + ZPVE(Mn)
$$
  
– [E<sub>tot</sub><sup>el</sup>(M<sub>n</sub><sup>-</sup>) + ZPVE(M<sub>n</sub><sup>-</sup>)]. (3)

The vertical electron detachment energies of the anion are computed at the geometry of the anion lowest total energy state according to the equation

$$
VDE_{\pm}(M_n^-) = E_{\text{tot}}^{\text{el}}(M_n, 2S + 1)
$$
  
-  $E_{\text{tot}}^{\text{el}}(M_n^-, (2S + 1) \pm 1).$  (4)

Experimental laser electron photodetachment spectra correspond to the vertical electron detachment processes. Experimental energies corresponding to the 0-0 electronic transitions (from the zero vibrational level of an anion to that of the neutral) provide good estimates for the adiabatic energies if the geometrical relaxation of the final neutral state is relatively small. Occasionally, it is difficult to recover the feature corresponding to the 0-0 transition in the spectra. In Table [III,](#page-8-1) which compares the computed and experimental values, the experimental entries without uncertainty bars correspond to approximate values obtained from the spectra without visibly resolved 0-0 transitions. As is seen from the table, our computed values are again within 0.1 eV from the corresponding experimental values when the experimental uncertainty bars are taken into account. Because our computed values for the ionization energies and electron affinities are in good agreement with experiment, we conclude that the lowest total energy states found for the  $M_{12}$  and  $M_{13}$  neutrals and their ions are to be close to the true ground states.

<span id="page-8-0"></span>TABLE II. Comparison of the BPW91/6-311+G\* values of the vertical (IE<sub>vert</sub>) and adiabatic ionization energies (IE<sub>ad</sub>) for the neutral M<sub>12</sub> and M<sub>13</sub> series with experiment. All values are in eV.

#### **C. Magnetic moments**

Total magnetic moments of *neutral* transition metal clusters were measured using Stern-Gerlach experiments for  $Sc_n$ ,  $n = 5-20$ ,  $27$  for  $Cr_n$ ,  $n = 20-133$ ,  $120$   $Mn_n$ ,  $121$   $Fe_n$ ,  $n = 10-25,^{122}$  Fe<sub>n</sub>,  $n = 25-700,^{123}$  $n = 25-700,^{123}$  $n = 25-700,^{123}$  Co<sub>n</sub>,  $n = 20-200,^{124}$  $n = 20-200,^{124}$  $n = 20-200,^{124}$  *n*  $= 12-200$ ,  $^{125}$   $n = 7-32$ ,  $^{126}$  $^{126}$  $^{126}$   $n = 13-200$ ,  $^{127}$  $^{127}$  $^{127}$  Ni<sub>n</sub>,  $n = 25-$ 700,<sup>[128](#page-12-42)</sup>  $n = 5-740$ ,<sup>[129](#page-12-43)</sup> and *cationic* transition metal clusters using X-ray magnetic circular dichroism (XMCD) experi-

ments for Fe<sub>n</sub><sup>+</sup>,  $n = 3-20$ ,<sup>[71](#page-12-2)</sup> and Co<sub>n</sub><sup>+</sup>,  $n = 8-22$ .<sup>[130](#page-12-44)</sup> Two branches of total magnetic moments per atom were found for  $Cr_n$  clusters<sup>120</sup> as well as for Fe<sub>n</sub> and Co<sub>n</sub> clusters.<sup>131</sup>

The total magnetic moment in the Russel-Saunders scheme is defined as  $\mu = (2S + L) \mu_B$ , where  $\mu_B$  is the Bohr magneton, and **L** and **S** are the total angular and spin moments, respectively. In the Heisenberg model, one neglects the **L** contribution and defines  $\mu = g_e \mu_B S$  where the

gyromagnetic ratio  $g_e$  is 2.0023. In the XMCD experiments performed for the  $Fe<sub>n</sub><sup>+</sup>$  and  $Co<sub>n</sub><sup>+</sup>$ , the contributions from both moments were separated whereas that was not possible in the Stern-Gerlach experiments. It was found for the iron cation series that "the orbital magnetic moment is strongly quenched and reduced to 5%–25% of its atomic value," $71$  whereas "an exceptionally strong enhancement of the orbital moment" was reported for the cobalt cation series.<sup>[130](#page-12-44)</sup> Theoretical estimates<sup>[132](#page-12-56)</sup> of the angular moment contributions for small  $\mathrm{Ni}_{n}$  clusters predicted these contributions to account for 20%–40% of total magnetic moments of the nickel clusters. We consider the total spin magnetic moment,  $M = 2S \mu_B$ , to be equal to  $[n_\alpha - n_\beta] \mu_B$ , where  $n_{\alpha}$  and  $n_{\beta}$  are the numbers of the majority spin and minority spin electrons, respectively.

Our values are compared to the experimental values of total magnetic moments and total spin magnetic moments obtained for the iron and cobalt cations in Table [IV.](#page-9-10) As is seen, there is good agreement for the iron cations, neutral cobalt species, and  $Co_{13}^+$ , whereas large differences remain in other cases. An especially large difference is obtained for Fe<sub>12</sub> where the experimental value of 5.2  $\mu$ <sub>B</sub> is larger than our computed value by 2.2  $\mu$ <sub>B</sub>. The possibility that the difference is due to a large orbital angular momentum contribution is discounted by the fact that such a contribution is small in the case of  $Fe_{12}^+$ .

<span id="page-9-11"></span>

Total spin magnetic moments per atom computed in this work are presented in Figs. [8](#page-9-11) and [9](#page-9-12) for the  $M_{12}$  and  $M_{13}$ series, respectively. The largest dependence on the charge is observed in the beginning of the  $M_{12}$  series, whereas small variations in the middle-to-end series are consistent with the one-electron rule. There is no visible dependence on the charge in the  $M_{13}$  series except for  $Fe_{13}^+$  whose total spin magnetic moment per atom is appreciably lower than that of Fe<sub>13</sub> or Fe<sub>13</sub><sup>-</sup>.

#### **D. Thermodynamic stability**

Experimental values obtained from mass-spectrometry measurements and our theoretical estimates for the  $D_0(M_{12})$  $-M$ ) and  $D_0(M_{12}^+ - M)$  energies corresponding to the removal of a single atom from the  $M_{13}$  and  $M_{13}$ <sup>+</sup> clusters, respectively, are compared in Table [V.](#page-10-0) Our theoretical values are computed as

<span id="page-9-13"></span>
$$
D_0(M_{12}^{0,+} - M) = E_{\text{tot}}^{el}(M_{12}^{0,+}) + \text{ZPVE}(M_{12}^{0,+}) + E_{\text{tot}}(M) - [E_{\text{tot}}^{el}(M_{13}^{0,+}) + \text{ZPVE}(M_{13}^{0,+})].
$$

The theoretical values are in relatively good agreement with the experiment. The difference between theory and experiment is within 0.5 eV if the experimental uncertainty bars are taken into account.

In order to compare binding energies per atom with the corresponding bulk values, we computed atomization energies of the neutral  $M_{12}$  and  $M_{13}$  clusters according to the

<span id="page-10-11"></span>

FIG. 10. Atomization energies for the lowest total energy states in the *M*2,  $M_{12}$ , and  $M_{13}$  series, the atom removal energies in the  $M_{13}$  series, and cohesive energies in the M bulk: (a)  $AE(M_2)$  are the atomization energies of the  $M_2$  dimers; AE( $M_{12}$ ) are the atomization energies of  $M_{12}$ ; AE( $M_{13}$ ) are the atomization energies of  $M_{13}$ ; (b)  $E(M_{12} - M)$  are the  $M_{12} - M$  dissociation energies; CE are the bulk cohesive energies.

expression

<span id="page-10-10"></span>
$$
E_{\text{atom}}(n) = \left[ E_{\text{tot}}^{\text{el}}(M_n) + \text{ZPVE}(M_n) - n E_{\text{tot}}(M) \right] / n. \quad (6)
$$

The values computed according to Eqs. [\(5\)](#page-9-13) and [\(6\)](#page-10-10) are presented in Fig. [10](#page-10-11) together with the dissociation energies of the  $M_2$  dimers,  $M =$  Sc−Zn computed<sup>133, [134](#page-12-58)</sup> at the same BPW91/6-311+ $G^*$  level, and bulk cohesive energies.<sup>135</sup> The dimer dissociation energies correspond to the smallest values for a given atom except for V, Cu, and Zn where the dimer dissociation energies are close to the atomization energies of  $V_n$ , Cu<sub>n</sub>, and Zn<sub>n</sub>, respectively. The  $M_{12} - M$  dissociation energies are closer to the corresponding bulk cohesive energies than the atomization energies and match the bulk values at V and Cr. All the curves possess the maxima at Ti, V, Fe, Ni, and Co (see the supplementary material $163$ ).

#### **IV. CONCLUSION**

We performed a systematic study of the structure, stability, electronic and magnetic properties of the neutral and singly negatively and positively charged 12- and 13-atom clusters of all 3*d*-metals from Sc to Zn using all-electron density functional theory with generalized gradient approximation. The main results obtained can be summarized as follows:

- (a) A number of members in the  $M_{12}$ ,  $M_{12}^-$ ,  $M_{12}^+$ ,  $M_{13}$ ,  $M_{13}$ <sup>-</sup>, and  $M_{13}$ <sup>+</sup> series ( $M =$  Sc−Zn) possesses multiple states which are close in total energy to the lowest total energy state. Several such cases were analyzed using larger basis sets and/or other exchange-correlation functionals. The results obtained using a larger basis set were qualitatively the same as those obtained using the  $6 - 311 + G^*$  basis set.
- (b) The lowest total energy states of the ions possess geometrical configurations that are different from those of their corresponding neutral parents in the  $V_{13}$ , Mn<sub>12</sub>,  $Co_{12}$ ,  $Ni_{13}$ ,  $Cu_{13}$ ,  $Zn_{12}$ , and  $Zn_{13}$  series.
- (c) The one-electron rule according to which an electron detachment or attachment from/to a neutral species results in the change of  $\pm 1.0 \mu_B$  in the total spin magnetic

moment is valid in all cases except for  $Sc_{12}^-$ ,  $Ti_{12}^+$ ,  $Mn_{12}^-$ ,  $Mn_{12}^+$ ,  $Fe_{12}^-$ ,  $Fe_{13}^+$ , and  $Co_{12}^+$ .

- (d) Our computed ionization energies of the neutrals and vertical detachment energies of the anions are within 0.1 eV from the experimental values if the experimental uncertainty bars are taken into account. Thus, the  $BPW91/6-311+G^*$  level of theory applied in the present work can be considered to be quite reliable.
- (e) The computed energies of a single atom removal  $[D_0(M_{12} - M)$  and  $D_0(M_{12}^+ - M)]$  are in satisfactory agreement with the experimental values possessing quite large uncertainty bars. The  $D_0(M_{12} - M)$  dissociation energies are found to be significantly larger than the dissociation energies of the  $M_2$  dimers and to be close to the corresponding bulk cohesive energies. In particular, the  $D_0$ (Ti<sub>12</sub> – Ti) and  $D_0$ (Mn<sub>12</sub> – Mn) values agree well with the corresponding bulk cohesive energies.

- <span id="page-13-7"></span>163See supplementary material at <http://dx.doi.org/10.1063/1.4799917> for two files (*M*<sup>12</sup> and *M*13) containing the short outputs of all 60 lowest total energy states shown in the figures. Each output provides optimized coordinates, harmonic frequencies, NAO populations, and total energies.
