This Event is brought to you for free and open access by the Dept. of Mathematics and Applied Mathematics at VCU Scholars Compass. It has been accepted for inclusion in Biology and Medicine Through Mathematics Conference by an authorized administrator of VCU Scholars Compass. For more information, please contact [libcompass@vcu.edu](mailto:libcompass@vcu.edu).

# Quantitative Electroencephalography for Detecting Concussions

Kathy Hoke\*    Sara Krehbiel†    Joanna Wares‡

March 13, 2018

## Abstract

To date, physicians have primarily used patients' self-report of injury and sequelae to diagnose concussions, or mild traumatic brain injuries (mTBIs). As a part of CENC, the Chronic Effects of Neurotrauma Consortium, we are working to determine physiological differences between patients who have incurred mTBIs and those who have not. We seek to identify predictors associated with long-term effects.

In our current work, we analyze quantitative electroencephalography (qEEG) data taken from service members and veterans of the Iraq and Afghanistan Wars. We develop a novel thresholding method for processing coherence data from qEEG to construct unweighted, undirected graphs representing brain connections. This method reduces the confounding effect of post traumatic stress disorder (PTSD), which is prevalent in this population. We test whether mTBI is associated with measures of local and long-range connectivity in these graphs, and we consider which graph properties predict the severity of postconcussive symptoms and/or impaired cognition. We find that brain networks of patients with severe mTBI are more dense but less structured (more random) than those without mTBI.
