Introduction

Sphingosine-1-phosphate (S1P), a lipid metabolite, has been recently demonstrated to be an important signaling mediator for vital cellular and physiological processes, such as cell motility, invasion, proliferation, angiogenesis and apoptosis [1,2]. S1P is produced from sphingosine via phosphorylation by two isoenzymes, sphingosine kinase-1 (SphK1) [3] and sphingosine kinase-2 (SphK2) [4]. Upon production, S1P interacts with a family of G protein-coupled receptors (S1PR1–5) on the cell surface [5] and/or intracellular targets, such as histone deacetylase (HDAC) [6] and TRAF2 [7], to play a plethora of roles in diverse pathophysiological conditions such as inflammation, immunity and cancer.

Ceramide and sphingosine, the precursors of S1P, have been demonstrated to be important signaling mediators for vital cellular and physiological processes, such as cell motility, invasion, proliferation, angiogenesis and apoptosis [1,2]. S1P is produced from sphingosine via phosphorylation by two isoenzymes, sphingosine kinase-1 (SphK1) [3] and sphingosine kinase-2 (SphK2) [4]. Upon production, S1P interacts with a family of G protein-coupled receptors (S1PR1–5) on the cell surface [5] and/or intracellular targets, such as histone deacetylase (HDAC) [6] and TRAF2 [7], to play a plethora of roles in diverse pathophysiological conditions such as inflammation, immunity and cancer.

Abstract

In our effort to develop selective sphingosine kinase-2 (SphK2) inhibitors as pharmacological tools, a thiazolidine-2,4-dione analogue, 3-(2-amino-ethyl)-5-[3-(4-butoxyl-phenyl)-propylidene]-thiazolidine-2,4-dione (K145), was synthesized and biologically characterized. Biochemical assay results indicate that K145 is a selective SphK2 inhibitor. Molecular modeling studies also support this notion. In vitro studies using human leukemia U937 cells demonstrated that K145 accumulates in U937 cells, suppresses the S1P level, and inhibits SphK2. K145 also exhibited inhibitory effects on the growth of U937 cells as well as apoptotic effects in U937 cells, and that these effects may be through the inhibition of down-stream ERK and Akt signaling pathways. K145 also significantly inhibited the growth of U937 tumors in nude mice by both intraperitoneal and oral administration, thus demonstrating its in vivo efficacy as a potential lead anticancer agent. The antitumor activity of K145 was also confirmed in a syngeneic mouse model by implanting murine breast cancer JC cells in BALB/c mice. Collectively, these results strongly encourage further optimization of K145 as a novel lead compound for development of more potent and selective SphK2 inhibitors.
shown to inhibit the xenograft growth of tumor cells in mice [15,19,20]. Recently, HDAC has been identified as an intracellular target of S1P, which is mainly produced by SphK2 within the nucleus and indicates a potential target of SphK2 in histone acetylation, gene expression, and cancer pathology [6]. SphK2 has also been demonstrated to play important roles in the function of mitochondria [21]. Even with these very recent advances in understanding of SphK2, much is still unknown or controversial about this kinase. Therefore, development of selective SphK2 inhibitors would be of great value as pharmacological tools to complement the ongoing molecular and genetic studies, and help unravel the roles of SphK2 in different pathological and physiological conditions. Although a number of potent and selective SphK1 inhibitors have been developed and reported [22–24], only a few SphK2 inhibitors with moderate potency, such as ABC 294640 (1) [19], SG-12 (2) [25], R-FTY720-OMe (3) [26] and trans-12 (4) [27], have been reported (Figure 1). Therefore, it would be of great value to have new and adaptable chemical scaffolds available as selective SphK2 inhibitors as this would help unravel the structural requirements for designing new SphK2 inhibitors.

Recently, our research group has initiated development of 3-[2-amino-ethyl]-thiazolidine-2,4-dione (TZD) analogues (5, Figure 2) as dual-pathway inhibitors of the ERK and Akt signaling pathways [28,29]. However, the cellular target(s) of these dual-pathway inhibitors remain unknown. Although the rhodanine- and TZD-compound types have been referred to as Pan Assay INterference compounds (PAINs) because of their frequent appearance as hits suggesting promiscuity [30], rhodanine and TZD analogues have also been recognized as privileged templates in drug design and discovery [31]. Recently, studies have also suggested that distinct, nonselective, interactions exist between them and biomacromolecules, and that these scaffolds should not be regarded as promiscuous binders, although diligence in examining selectivity for moderate affinity compounds with these functional groups is advised [32]. Numerous compounds containing the TZD ring have already been developed as potential anticancer agents, such as the PI3K inhibitor GSK1059615 and its analogues [33].

In comparing it to sphingosine (6), the 3-[2-amino-ethyl]-TZD moiety of our dual-pathway inhibitors may be able to mimic the amino-hydroxyl sphingoid base. Furthermore, SphK inhibitors have been shown to inhibit the ERK and Akt signaling pathways as a downstream event of SphK inhibition [10,23,24]. These observations suggested to us that SphKs might be protein targets of the TZD-based dual-pathway inhibitors. Furthermore, previous studies suggested that a phenyl ring with an alkyl chain is an important structural feature as SphK inhibitors [24]. Therefore, we report herein the design and biological characterization of K145. 3-[amino-ethyl]-5-[3-(4-butoxy-phenyl)-propylidene]-thiazolidine-2,4-dione (7, Figure 2) as a selective SphK2 inhibitor.

Results and Discussion

Chemistry

The synthesis of K145 is shown in Figure 3. Briefly, 3-(4-butoxy-phenyl)-propionaldehyde (10) was prepared from 4-butoxy-benzaldehyde (8) by reacting with Meldrum’s acid in the presence of piperidine followed by reduction [29]. Then, the condensation reaction of 10 with 13, prepared from thiazolidine-2,4-dione, followed by the removal of the Boc protecting group afforded K145 in good yield.

In vitro Studies

After synthesis, we first examined the effects of K145 on recombinant SphK1 and SphK2. Notably, K145 inhibited the activity of SphK2 in a dose-dependent manner with an IC_{50} of 4.30±0.06 μM (Figure 4A), while no inhibition of SphK1 at concentrations up to 10 μM was observed. In contrast, and as expected, DMS (10 μM), a non-selective SphK inhibitor, inhibited both SphK1 and SphK2. Thus, K145 is a selective SphK2 inhibitor. Lineweaver-Burk analysis revealed a K_i of 6.4±0.7 μM for SphK2 and indicated that K145 is a substrate competitive inhibitor (with sphingosine) (Figure 4B). The overlay of K145 with sphingosine also supports these results (Figure 4C). Since K145 is a sphingosine analogue, we then tested it against ceramide kinase (CERK) to confirm selectivity. As shown in Figure 4D, at a concentration up to 10 μM, no significant inhibition of CERK was observed. Further screening against eleven other protein kinases (Figure 4E) also demonstrated the relative selectivity of K145 to SphK2.

Next we examined whether K145 affects cellular levels of S1P. Human leukemia U937 cells have been demonstrated to be a good model to test compounds that interfere with the SphK/S1P system and it has previously been shown that S1P is protective against apoptosis of U937 cells [9,23,24,34]. Therefore, we further characterized K145 in U937 cells. As shown in Figure 5A, K145 is readily taken up by U937 cells in a concentration dependent manner. In agreement with its ability to inhibit SphK2,
but not ceramide kinase (Figure 4D), as shown in Figures 5B and 5C, treatment with K145 (10 μM) caused a decrease of total cellular S1P without significant effects on ceramide levels. The inhibitory potency of K145 on cellular level of S1P is somewhat less than its IC_{50} (4.3 μM) determined at recombinant SphK2. This might be due to the fact that many enzymes such as SphK1, SphK2, S1P lyase, and S1P phosphatise, not just SphK2, are involved in the regulation of cellular S1P. The level of ceramide-1-phosphate (C1P) was not significantly affected upon treatment with K145 (10 μM, Figure 5D), which indicates that K145 does not interfere with CERK and/or ceramide synthase, consistent with the results from recombinant CERK studies. To further confirm its SphK2 selectivity, we then tested the effects of K145 on the phosphorylation of FTY720, a SphK2 specific substrate [35]. As shown in Figure 5E, K145 inhibited the phosphorylation of FTY720, which further indicates the SphK2 specificity of K145. SphK2 inhibitors have been shown to have anti-proliferative activities in cancer models both in vitro and in vivo [19,20]. SphK2 has also been recently shown to play a role in mitochondria function and apoptosis. Therefore, we tested the anti-proliferative and apoptotic effects of K145 in U937 cells. As shown in Figure 6A, K145 significantly inhibited the growth of U937 cells cultured in the presence of 10% serum in a concentration-dependent manner. In agreement with our study, others using a different SphK2 inhibitor ABC294660 [20], or downregulation of SphK2 [15] also observed effects on cell proliferation, while treatment with another SphK2 inhibitor SLR0801 caused only a small decrease in cell viability [36]. K145 also significantly induced apoptosis in U937 cells under these experimental conditions (Figure 6B). Notably, K145 induced mainly late apoptosis with a very small percentage of necrotic cells after 24 h treatment in the presence of 10% serum. In contrast, the SphK1 inhibitor SK1-I mainly induced early apoptosis of U937 cells after similar treatment (24 h in the presence of 10% serum) [24]. This suggests that SphK1 and SphK2 may have different roles in the regulation of apoptosis, at least for U937 cells.

S1P has been shown to activate the downstream ERK and Akt signaling pathways [37,38] and these two signalling cascades have been demonstrated to cooperatively link with each other to regulate apoptosis and the survival of transformed cells including human leukaemia cells [39]. As shown in Figure 6C, phosphorylated ERK and Akt were decreased by treatment of U937 cells...
with K145, consistent with our previous results with TZD analogues as dual-pathway inhibitors [28,29]. Notably, the inhibition of these two signaling pathways is evident at as low as 4 μM of K145, consistent with its IC50 values of SphK2 inhibition and anti-proliferation of U937 cells. Studies have demonstrated the synergistic effects in triggering cancer cell death by concomitant interruption of these two pathways, both in vitro and in vivo using a combination regimen [40]. The simultaneously inhibitory effects of K145 on ERK and Akt pathways upon its inhibition of SphK2 may explain its significant anti-proliferative and apoptotic effects in U937 cells.

Molecular Modeling

To further understand the SphK2 selectivity of K145, we conducted molecular modeling studies to identify the structural features of K145 that interact with key residues of SphK2. Since no crystal structure is currently available for either SphK1 or SphK2, we generated structural models of SphK1 and SphK2 using MODELLER [41], a comparative protein structure modeling program, using the structure of Diacylglycerol kinase from Bacillus anthracis str. Sterne [PDB ID: 3T5P] as a template [42,43]. The overall structural geometries of the resulting models were checked using MOLPROBITY [44] (clash scores for both proteins 97th percentile) and the Ramachandran plots for the backbone conformations showed 96% of residues in allowed regions for both isoforms. Despite low overall homology to the template (46% in aligned regions for both isoforms), there is considerable sequence and structural similarity at the sphingosine-binding (C4) domain [45], and we believe that these models provide valuable structural information.

Figure 4. K145 inhibits SphK2 but not SphK1. A) SphK1 and SphK2 activities were measured with 5 μM sphingosine in the absence or presence of the indicated concentrations of K145 or 10 μM DMS. Data are expressed as percentage SphK activity in the absence of inhibitor; B) SphK2 activity was measured with increasing concentrations of sphingosine and the indicated concentrations of K145. Lineweaver-Burk analysis revealed a Vmax of 10820 ± 210 pmol/min per mg of protein, and a Ki of 6.4 ± 0.7 μM for SphK2; C) Overlay of K145 with sphingosine; D) CERK activities were measured with 12.5 μM ceramide in the absence or presence of the indicated concentrations of K145 or 100 μM of DMS and sphingosine; E) Effect of K145 (10 μM) on activity of the indicated enzymes was tested by SelectScreen Kinase Profiling from Invitrogen. Data are expressed as percentage of control activity averaged from 2 independent experiments. Data are expressed as mean value ± SEM.

doi:10.1371/journal.pone.0056471.g004
binding sites for SphK2 and SphK1 were defined to encompass all atoms within 20 Å of the CA of Asp344 and Asp178, respectively. Docked poses were generated using GOLD [48] v5.1 and rescored using HINT [49]. The best scoring docked positions for each ligand were selected for minimization (2500 iterations, termination gradient of 0.005 kcal/mol-Å). As shown in Table 1, the relative ordering of HINT scores (HTOT) are largely in concordance with the reported binding/inhibitory observations (Table 1). [50,24–27].

We then docked K145 to the two kinase models. The docking results revealed that K145 binds preferentially to SphK2 (Table 1). Specifically, as shown in Figure 7, our model indicates that the terminal –NH2 of K145 forms strong H-bond interactions with the carboxylate group of Asp344 (the putative sphingosine recognizing residue). Other favourable hydrogen bonding interactions are also formed between the guanidino-group of Arg351 and Gln346 with the carbonyl oxygens of the TZD heterocycle. The TZD ring of K145 shows favourable π-stacking interactions with Phe350 and the 4-butoxy-phenyl ring of K145 fits into a hydrophobic pocket that consists of Ala336, Val340, Val343, Arg617 and Val619. K145 showed a very similar binding mode within the sphingosine-binding pocket of SphK1 except that, in contrast to its binding mode in SphK2, the carbonyl oxygen at the 4-position of the TZD ring (interacting with Gln346 in SphK2) showed unfavourable base/base interactions with the carboxylate group of Glu180 (corresponding to SphK2/Gln346). Judging from the sequence similarity in the sphingosine-binding domains of both isoforms, the Gln→Glu change in SphK1 is the only significant difference in this region and might be the reason for K145 showing selectivity towards SphK2.

**In vivo Studies**

Downregulation of SphK2 or application of a SphK2 inhibitor have shown anti-tumor effects both *in vitro* and *in vivo* [15–20] and we have shown the anti-proliferative and apoptotic effects of K145 in U937 cells; thus, we evaluated the ability of K145 to inhibit the growth of U937 tumors in nude mice. Tamibarotene [51], a retinoid compound that has been approved for acute promyelocytic leukemia in Japan, was used as a positive control. Both tamibarotene and K145 were given at a 15 mg/kg dose by i.p. injection. As shown in Figure 8A, K145 significantly inhibited the

**Figure 5. K145 accumulates and suppresses the S1P level.** A and B) U937 cells were treated with K145 at the indicated concentrations for 3 h and the levels of K145 and S1P were measured by ESI-MS/MS. C) HEK293 cells were treated with K145 (10 μM) for 2 h. Lipids were extracted and different chain length species of ceramide were determined by LC-ESI-MS/MS. Numbers indicate chain length followed by the number of double bonds in the fatty acid. Data are averages of triplicate determinations and are expressed as pmol lipid/10^6 cells. D) U937 cells were treated with or without K145 (10 μM) for 3 h and levels of C1P species were determined by ESI-MS/MS. E) U937 cells were treated with FTY720 (1 μM) in the absence or presence of indicated K145 for 3 h, then FTY720-P was measured by ESI-MS/MS. *P<0.05 compared to control.

doi:10.1371/journal.pone.0056471.g005
growth of U937 tumors in nude mice with a TGI of 44.2%, slightly less potent than tamibarotene (TGI = 50.4%) after 17 days treatment. This is also reflected by the tumor weights of treatment groups (Figure 8B). The tumor growth curve during the treatment course (Figure 8C) also attests to the anti-tumor effects of K145 in this model. Lastly, as shown in Figure 8D, the body weights of K145-treated mice remained the same as that of vehicle-treated mice, while tamibarotene treatment caused body weight decreases in the mice. These results strongly suggest that K145 exhibits comparable in vivo anti-tumor activity to tamibarotene, while concomitantly exhibiting less toxicity in this U937 xenograft cancer model.

On the basis of this in vivo anti-tumor activity in nude mice, we attempted to further confirm K145’s in vivo anti-tumor activity using a syngeneic breast cancer model. In this regard, we selected a tumor model that uses the mouse JC mammary adenocarcinoma cell line growing subcutaneously in immunocompetent BALB/c mice [19,52]. Since K145 demonstrated in vivo activities at 15 mg/kg dose in the nude mice experiment, we used two doses, 20 mg/kg and 35 mg/kg through i.p. injection in this model. As illustrated in Figure 9A, treatment of BALB/c mice (n = 8) bearing the JC xenograft significantly inhibited tumor growth at both doses with the higher dose being more potent. After 15 days treatment, the mean volume of the JC tumors in the treated-mice at both doses was >50% smaller than that in the vehicle-treated mice. Tumor weights of K145-treated mice were also significantly less than that in vehicle-treated mice in a dose-dependent manner (Figure 9B). Post-experiment visual evaluation of the tumor samples also confirms the results (Figure 9D). We analyzed the tumor samples to detect K145, the change of S1P by ESI-MS/MS and the change of signaling pathways by Western blot. As shown in Figure 9C, K145 was detected in JC tumors and the S1P level was suppressed compared to vehicle, consistent with the results from U937 cells assays. Notably, the p-ERK and p-Akt levels were

Figure 6. K145 exhibits antiproliferative and apoptotic effects in U937 cells. A) U937 cells were treated with K145 at indicated concentrations for indicated intervals, the cell viability was determined by MTT assay; B) U937 cells were treated with K145 (10 μM) for 24 h, then the cells were stained with Annexin V/PI and analyzed by flow cytometry; C) U937 cells were treated with K145 at indicated concentrations for 3 h, after which cell lysates were analyzed by Western blot using corresponding primary antibodies. The image of Western blot represents the results from one of two independent experiments. Data are expressed as mean value ± SEM. doi:10.1371/journal.pone.0056471.g006
decreased in the tumor samples compared to the vehicle controls (Figure 9E), which is consistent with the results from U937 cells (Figure 6C). We did not observe significant changes in body weights and the major organs, such as heart, lung, liver and kidney (data not shown), thus indicating a lack of general toxicity of K145.

Lastly, we examined the anticancer activity of K145 to inhibit the tumor growth of U937 cells in nude mice (BALB/c-nu) by oral administration to investigate whether it is orally available. In this experiment, K145 was given at 50 mg/kg by oral gavage daily for 15 days and tumor volume and animal weights were measured every other day. Again, tamibarotene (20 mg/kg) was used as positive control. As shown in Figure 10A, tumor weights of K145-treated mice were significantly less than that in vehicle-treated mice and K145 exhibited better antitumor activity than tamibarotene at tested doses by oral administration (TGI for K145 and tamibarotene are 51.25% and 33.37%, respectively). Visual examination of the tumor samples also confirmed the significant inhibition of U937 tumor growth by K145 (Figure 10B). Tumor growth curve also demonstrated the superior anti-tumour activity of K145 in these experimental settings (Figure 10C). As shown in Figure 10D, at the beginning of the treatment, there was a slight decrease of body weights in K145-treated group but the body weights of this group came back in the remaining course of the study. Collectively, the results of in vivo studies with K145 by oral administration demonstrated that K145 is orally available to inhibit the growth of U937 tumors at 50 mg/kg dose and no apparent toxicity was observed, which is consistent with the results from in vivo studies by i.p. injection administration. To summarize, all in vivo results we have obtained strongly suggest that K145 has in vivo anti-tumor activity, thus it may serve as a good lead compound for development of more potent and selective SphK2 inhibitors and new anticancer agents.

**Conclusions**

K145 was identified as a selective SphK2 inhibitor. Biochemical assays using recombinant SphK1 and SphK2 established that K145 selectively inhibited SphK2 but not SphK1. Molecular modeling and docking studies also suggested that K145 favorably binds to SphK2 but not SphK1 within their respective sphingosine binding pockets, consistent with the biochemical assay results. Further biological characterization using human leukemia U937 cells demonstrated that K145 accumulated in U937 cells and inhibited the phosphorylation of FTY720. Furthermore, K145 inhibited the growth of U937 cells, mainly through apoptotic effects. It is well documented that the activation of SphK/S1P system leads to the activation of survival signaling pathways including the ERK and Akt cascades. Moreover, like K145, TZD analogues are known to be dual-pathway inhibitors [28,29]. Consistent with this notion, K145 significantly inhibited the phosphorylation of ERK and Akt upon treatment of U937 cells and the deactivation of ERK and Akt might contribute to its anti-tumor effects.

apoptotic effects as these two signalling pathways have been closely linked to apoptosis in leukemia cells. Most importantly, K145 was shown to significantly suppress the growth of U937 tumors in nude mice through both intraperitoneal and oral administration without apparent toxicity, thus attesting to its oral bioavailability and in vivo anti-tumor activity. The use of a syngeneic tumor model further confirmed that K145 significantly inhibited the growth of JC tumor cells in BALB/c mice at both 20 and 35 mg/kg doses, again without apparent toxicity. These results encourage further optimization of K145 as a novel lead compound to develop more potent and selective SphK2 inhibitors. Our results may also suggest that development of novel thiazolidine-based inhibitors may provide effective compounds as anticancer agents.

Materials and Methods

Chemistry

Reagents and solvents were obtained from commercial suppliers and used as received unless otherwise indicated. All reactions were carried out under inert atmosphere (N₂) unless otherwise noted. Reactions were monitored by thin-layer chromatography (TLC) (precoated silica gel 60 F₂₅₄ plates, EMD Chemicals) and visualized with UV light or by treatment with Phosphomolybdic acid (PMA). Flash chromatography was performed on silica gel (200–300 mesh, Fisher Scientific) using solvents as indicated. ¹H NMR and ¹³CNMR spectra were routinely recorded on Bruker ARX 400 spectrometer. The NMR solvent used was CDCl₃ or DMSO-d₆ as indicated. Tetramethylsilane (TMS) was used as internal standard. The purity of target compound was determined by elemental analysis.

5-(4-butoxybenzyl)-2,2-dimethyl-1,3-dioxane-4,6-dione (10). To a stirred solution of 4-butoxybenzaldehyde (891.0 mg, 5.0 mmol) and Meldrum's acid (720.0 mg, 5.0 mmol) in EtOH (5.0 mL) was added piperidine (two drops). The resulting solution was stirred at room temperature overnight and suction filtration gave a light yellow solid (731.0 mg). To the mixture of the yellow solid and acetic acid (3.0 mL) in CH₂Cl₂ (20.0 mL) was added sodium borohydride (314.0 mg, 8.4 mmol) at 0°C. The resulting solution was stirred at room temperature for 1 h, diluted with CH₂Cl₂ (30.0 mL) and washed with brine and water. The organic layer was then dried over anhydrous Na₂SO₄. After filtration, the mixture was concentrated under vacuum and the residue was purified by flash column chromatography (hexane:acetone = 5:2) to give 10 as a light yellow solid, 28% yield. ¹H NMR (400 MHz,
CDCl3): 7.23–7.21 (d, J = 8.6 Hz, 2H), 6.82–6.79 (d, J = 8.6 Hz, 2H), 3.92 (t, J = 6.5 Hz, 2H), 3.71 (t, J = 4.8 Hz, 1H), 3.44–3.43 (d, J = 4.8 Hz, 2H), 1.76–1.70 (m, 5H), 1.50–1.44 (m, 5H), 0.96 (t, J = 7.4 Hz, 3H).

4-butoxyphenyl-3-propanal (11). To a solution of compound 10 (368.0 mg, 1.2 mmol) in THF (7.0 mL) was added Et3N (0.3 mL, 2.4 mmol) followed by phenylsilane (0.4 mL, 3.6 mmol). The resulting solution was stirred for 2 h at room temperature. Water was added to the solution and stirred for 15 min. The reaction mixture was diluted with diethyl ether (15.0 mL) and washed with water and brine. The organic layer was dried over anhydrous Na2SO4 overnight. After filtration, the filtrate was concentrated and the residue was purified by flash column chromatography (hexane/acetone = 10/1) to give 11 as a light colorless oil, 81% yield. 1H NMR (400 MHz, CDCl3): 9.81 (t, J = 1.5 Hz, 1H), 7.10–7.08 (d, J = 8.6 Hz, 2H), 6.83–6.81 (d, J = 8.6 Hz, 2H), 3.93 (t, J = 6.5 Hz, 2H), 2.90 (t, J = 7.5 Hz, 1H), 2.76–2.72 (m, 2H), 1.77–1.71 (m, 2H), 1.55–1.43 (m, 2H), 0.97 (t, J = 7.4 Hz, 3H).

4-butyl 2-bromoethylcarbamate (13). To a solution of bromoethylamine hydrobromide (20.5 g, 100.0 mmol) in CH2Cl2 (200.0 mL) was added triethylamine (13.9 mL, 100.0 mmol) dropwise at 0°C. After addition, the mixture was stirred at room temperature overnight, and then water was added. The separated CH2Cl2 layer was washed with brine, and dried over anhydrous Na2SO4. Removal of the solvents gave 13 as colorless oil, 89% yield. 1H NMR (400 MHz, CDCl3): 8 4.95 (s, 1H), 3.54–3.53 (m, 2H), 3.47–3.45 (m, 2H), 1.45 (s, 9H).

4-butyl 2-(2,4-dioxothiazolidin-3-yl)-ethylcarbamate (14). A mixture of thiazolidine-2,4-dione (7.9 g, 68.0 mmol), 13 (17.9 g, 92.0 mmol), and TBAI (2.5 g, 6.8 mmol) in acetone (100.0 mL) was stirred at 40°C for 10 h. The reaction mixture was cooled to room temperature and filtered through a short bed of celite. The filtrate was concentrated under vacuum and the residue was purified by flash chromatography (Hexane/EtOAc = 4/1 to 2/1) to give 14 as white solid, 70% yield. 1H NMR (300 MHz, CDCl3): 3.94 (s, 2H), 3.78–3.74 (t, J = 6.0 Hz, 2H), 3.40–3.34 (t, J = 6.0 Hz, 2H), 1.43–1.39 (m, 2H), 1.34–1.28 (m, 2H), 1.26–1.20 (m, 2H), 1.16–1.09 (m, 2H), 0.97–0.90 (m, 2H), 0.89–0.83 (m, 2H), 0.81–0.75 (m, 2H), 0.74–0.68 (m, 2H), 0.67–0.61 (m, 2H), 0.60–0.54 (m, 2H), 0.53–0.47 (m, 2H), 0.46–0.40 (m, 2H), 0.39–0.33 (m, 2H), 0.32–0.26 (m, 2H), 0.25–0.19 (m, 2H), 0.18–0.12 (m, 2H), 0.11–0.05 (m, 2H), 0.04–0.00 (m, 2H).

3-(2-aminoethyl)-5-(3-(4-butoxyphenyl)propylidene)thiazolidine-2,4-dione (7). A solution of 14 (2.0 g, 7.7 mmol), 4-butoxyphenyl-3-propanal (1.9 g, 7.7 mmol) and piperidine (0.2 mL, 3.6 mmol) in EtOH (60.0 mL) was stirred at room temperature overnight. The solvents were removed and the residue was purified by flash column chromatography (hexane/EtOAc = 9/1) to give 7 as white solid, 61% yield. 1H NMR (400 MHz, CDCl3): 8 10.05 (s, 1H), 7.33–7.29 (d, J = 8.6 Hz, 2H), 6.81–6.78 (d, J = 8.6 Hz, 2H), 3.91 (t, J = 6.5 Hz, 2H), 3.71 (t, J = 4.8 Hz, 1H), 3.44–3.43 (d, J = 4.8 Hz, 2H), 1.76–1.70 (m, 5H), 1.50–1.44 (m, 5H), 0.96 (t, J = 7.4 Hz, 3H).

Figure 9. K145 suppresses the growth of JC xenograft in BALB/c mice. BALB/c mice (n = 8) with palpable JC xenograft were treated daily with vehicle or K145 (20 mg/kg and 35 mg/kg) for 15 days by i.p. injection. A) Tumor volumes were measured every other day; B) After treatment, animals were sacrificed and tumors were removed and weighed; C) The S1P and K145 levels in the tumor samples from vehicle and treatment (20 mg/kg) groups (n = 4) were measured by ESI-MS/MS; D) Images of tumor samples from control and treatment groups (n = 7 for each group) after the experiments; E) Tumor samples (20 mg/kg and control groups) were analyzed by Western blot. Data are expressed as mean value ± SEM. *P < 0.05 compared to control group.

doi:10.1371/journal.pone.0056471.g009
removed under vacuum and the residue was purified by flash column chromatography (hexane/EtOAc = 8/1) to give t-butyl 2-(5-((3-(4-butoxyphenyl)propylidene)-2,4-dioxothiazolidin-3-yl)ethyl)carbamate as a white solid, 60% yield. 1H NMR (400 MHz, CDCl3): 7.10–7.06 (m, 3H), 6.85–6.80 (d, J = 8.6 Hz, 2H), 4.72 (s, 1H), 3.94 (t, J = 6.5 Hz, 2H), 3.81 (t, J = 5.5 Hz, 2H), 3.39–3.38 (m, 2H), 2.78 (t, J = 7.4 Hz, 2H), 2.53–2.48 (q, J = 7.6 Hz, 2H), 1.80–1.72 (m, 2H), 1.49–1.44 (m, 2H), 1.40 (s, 9H), 0.97 (t, J = 7.4 Hz, 3H). To a stirred solution of t-butyl 2-(5-((3-(4-butoxyphenyl)propylidene)-2,4-dioxothiazolidin-3-yl)ethyl)carbamate (2.3 g, 4.7 mmol) in EtOAc (20.0 mL) was added 4 M HCl in dioxane (6.0 mL), the solution was stirred at room temperature for 5 h. The precipitate was collected by filtration to give the HCl salt of 7 as white solid, 75% yield. 1H NMR (400 MHz, DMSO-d6): 8.08 (brs, 3H), 7.15–7.13 (d, J = 8.5 Hz, 2H), 7.01 (t, J = 7.4 Hz, 1H), 6.86–6.84 (d, J = 8.3 Hz, 2H), 3.92 (t, J = 6.4 Hz, 2H), 3.83 (t, J = 6.0 Hz, 2H), 3.00 (m, 2H), 2.76 (t, J = 7.3 Hz, 2H), 2.53–2.48 (m, 2H), 1.69–1.64 (m, 2H), 1.45–1.39 (m, 2H), 0.92 (t, J = 7.3 Hz, 3H); 13C NMR (100 MHz, DMSO-d6): 167.5, 164.4, 157.1, 137.3, 131.9, 129.2, 125.1, 114.3, 66.9, 36.5, 32.9, 32.1, 30.7, 18.6, 13.6. Anal. (C18H25ClN2O3S) Calcd. C: 56.17%, H: 6.55%, N: 7.28%; found C: 55.91%, H: 6.69%, N: 7.14%, S: 8.16%.

Homology and Molecular Modeling

Human SphK1 (Accession: Q9NYA1) and SphK2 (Accession: NP_001191088) sequences were obtained from the NCBI database (www.ncbi.nlm.nih.gov/protein/). A Position Specific Iterated BLAST [42,43] search against the database of Protein Data Bank proteins identified a kinase – diacylglycerol kinase from Bacillus anthracis str. Sterne (PDB ID: 3T5P), as the closest match to both proteins with ~25% identity and ~46% homology in the aligned regions to both isoforms of SphK. Sequence alignments of each SphK1 and SphK2 with 3T5P were performed using CLUSTALX2 [53]. Unaligned regions in both the proteins were deleted. A total of 100 homology models for each isoform were generated based on these alignments, using MODELLER 9v10 [54]. The top 5 models for each kinase with the lowest DOPE (Discrete Optimized Protein Energy) scores and molpdf scores (a MODELLER object function score) and with GA341 [55] scores closest to 1 were chosen for further refinement. The side chains for each model were optimized using SCWRL (dunbrack.fccc.edu/scwrl4/). Hydrogens were added to these top models using SYBYL (www.tripos.com) and subsequently subjected to Powell minimization for 10000 iterations in the Tripos force field with a 0.005 kcal/mol-Å termination gradient. The quality of minimized models was evaluated using MOLPROBITY (molprobity.-
biochem.duke.edu/), which performs an all-atom contact analysis to give a ‘clashscore’ that is indicative of the number of serious clashes (>0.4 Å) per 1000 atoms. Poor side-chain rotamers and unreasonable bond lengths and angles were checked. Ramachandran plots were also generated using MOLPROBITY to check the backbone-geometry of the models. Atom clashes and bad bond lengths and angles were optimized with further minimization.

Sphingosine, the natural substrate for both kinases, was docked into the C4 domain (putative Sph binding domain, Leu163–Phe197 for SphK1 and Cys289–Val363 for SphK2 [56]) of each model, using GOLD v5.1 [48]. The docked poses were scored using HINT [49]. The ‘best’ model of both SphK1 and SphK2 was then chosen based on its overall stability and its ability to accommodate Sphingosine in its C4 domain. Model-044 was the best model for SphK1, with a clashscore of 3.2 (97th percentile) and with 96.8% residues in allowed regions on Ramachandran plots. Model-055 was the best model for SphK2, with a clashscore of 2.03 (99th percentile) and with 98.5% residues in allowed regions on Ramachandran plots.

The optimized models of both SphK1 and SphK2 were used for the docking studies. The structures of inhibitors were sketched using SYBYL v8.1, and subjected to minimization to obtain low energy structures. The docking simulations were performed using GOLD v5.1. The binding site was defined to encompass all atoms within 20 Å of CA of Asp178 of SphK1 (Asp344 of SphK2). Fifty solutions for each inhibitor molecule were generated with a protein hydrogen-bond constraint that the carboxylate of Asp178 of SphK1 (Asp344 of SphK2) forms a hydrogen bond with ligand, since the Asp is important for recognition of Sphingosine [48]. The docked poses were scored using HINT. The poses with the best HINT scores were complexed with the protein and the protein–ligand complex was subjected to minimization, to remove steric clashes and get an induced-fit model. The binding modes of the ligands after minimization were re-scored using HINT.

Cell Culture

Human leukemia U937 cells and murine JC mammary cells were obtained from American Type Culture Collection (ATCC, Manassas, VA) and cultured in RPMI 1640 medium (Life Technologies, Inc., Grand Island, NY) supplemented with 10% (v/v) of heat-inactivated fetal bovine serum (FBS, HyClone, Logan, UT). Cells were maintained at 37°C in a fully humidified atmosphere containing 5% CO2. All reagents were prepared and used as recommended by their suppliers.

SphK Activity

Lysates from cells overexpressing SphK1 or SphK2 were used for determining the effects of inhibitors on enzyme activity [11]. SphK1 activity was determined in the presence of 5 μM sphingosine and [γ-32P]ATP (10 μCi, 1 mCi) containing MgCl2 (10 mM) in 0.25% Triton X-100, which inhibits SphK2, as described previously [11]. SphK2 activity was determined with sphingosine added as a complex with 4 mg/ml BSA and [γ-32P]ATP in the presence of 1 γ KCl, conditions in which SphK2 activity is optimal and SphK1 strongly inhibited [18].

Ceramide Kinase Assay

Ceramide and human recombinant ceramide kinase (CERK) were obtained from BPS bioscience, Kinase-Glo luminescent assay regents were obtained from Promega. Assays were carried out on 96 wells plate at 50 μL scale in triplicate. For each well, compounds, 15 μM ceramide (prepared freshly according to the manufacturer’s instruction), and 40 ng CERK were incubated at RT for 5 min, the reaction was started by addition of ATP (5 μM final concentration). Incubated at 37°C for 25 min, 50 μL of Kinase-Glo luminescent regent was added and incubated at RT for 10 min. The luminescence was recorded by a FlexStation 3 plate reader (Molecular Devices, CA).

Lipidomics Analysis

Four million U937 cells were treated by K145 for 3 h. Cells were collected and washed with PBS and analyzed by LC-MS/MS. For influence of FTY720-P formation, 4 million U937 cells were incubated with K145 together with 1 μM FTY720 for 3 h, then cells was collected and washed with PBS and analyzed by LC-MS/MS as described previously [57].

Cell Proliferation Assays

U937 cells (20,000 cells/well) were plated into 96-well plate and treated with K145 for 72 h. Then 10 μL of MTT [3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide 5 mg/mL in PBS] was added and cells incubated for an additional 2 h at 37°C in a fully humidified atmosphere containing 5% CO2. After centrifuge, medium (170 μL) was removed and DMSO (100 μL) was added to each well. The absorbance was read by a FlexStation 3 plate reader (Molecular Devices, CA) at a wavelength of 570 nm. Values were expressed as a percentage relative to those obtained in untreated controls.

Apoptosis Assay

U937 (1×10⁴) cells were treated with K145 at indicated concentrations and indicated intervals, then cells were collected and washed twice with cold PBS. Cells were resuspended in buffer containing 10 mM HEPES [N-2-hydroxyethylpiperazine-N’-2-ethanesulfonic acid]/NaOH, pH 7.4, 140 mM NaOH, and 2.5 mM CaCl2. The cells were incubated with annexin V-fluorescein isothiocyanate (FITC) (BD PharMingen, San Diego, CA) and propidium iodide (PI) for 15 min at room temperature per manufacturer’s instruction. The samples were analyzed by flow cytometry using a Beckton Dickinson FACSCanto machine within 1 h to determine the percentage of cells displaying annexin V-FITC staining (early apoptosis) or both annexin V-FITC and PI staining (late apoptosis).

Western Blotting

U937 Cells (2×10⁷/mL) were treated with K145 at indicated concentration for 1 h in the presence of 10% PBS. Cells were lysed by sonication in sample buffer [62.5 mM Tris base (pH 6.8), 2% SDS, 50 mM DTT, 10% glycerol, 0.1% bromphenol blue, and 5 mg/mL each chymostatin, leupeptin, aprotinin, pepstatin, and soybean trypsin inhibitor] and boiled for 5 min. For analysis of phospho-proteins, no SDS was included in the transfer buffer. The proteins were electrotransferred onto a PVDF membrane (Bio-Rad). For blotting phosphoproteins, no SDS was included in the transfer buffer. The blots were blocked with 5% nonfat dry milk in TBS-Tween 20 (0.1%) at room temperature for 1 hour and probed with the appropriate dilution of primary antibody overnight at 4°C. The blots were washed twice with TBS-Tween 20 for 15 min and then incubated with a 1:2000 dilution of horseradish peroxidase-conjugated secondary antibody (Kirkegaard & Perry, Gaithersburg, MD) in 5% nonfat dry milk/TBS-Tween 20 at room
temperature for 1 h. After washing twice in TBS-Tween 20 for 15 min, the immunopositive bands were visualized with Western Blot Chemiluminescence Reagent (NEN Life Science Products, Boston, MA). Where indicated, the blots were re-probed with antibodies against another GAPDH to ensure equal loading and transfer of proteins. The following antibodies were used as primary antibodies: Cell Signaling: MA: phospho-p44/42 MAPK (Thr202/ Tyr204) antibody (1:1000, rabbit polyclonal), p44/42 MAPK antibody (1:1000, rabbit polyclonal), phospho-Akt (Ser473) antibody (1:1000, rabbit polyclonal), Santa Cruz, CA: Akt1/2/3 (H-136) (1:1000, rabbit polyclonal).

In vivo Antitumor Evaluations

All experiments involving animals were carried out in strict accordance with the recommendations in the Guidelines and Regulations of Institutional Animal Care and Use Committee (IACUC) of the Virginia Commonwealth University (VCU). The protocol was approved by the Committee on the Ethics of Animal Experiments of VCU (IACUC Number: AM10206). For U937 xenograft studies, female BALB/c-nu nude mice (Charles River, NC) were maintained under specific pathogen-free conditions. Human leukemia U937 cells (1 x 10^4, ATCC, Manassas, VA) in logarithmic growth phase were implanted in the right flanks of each mouse. Once the U937 xenografts reached a palpable size, mice were randomly assigned to control group or treatment groups (n = 7). Compound K145 and Tamibarotene were administered via intraperitoneal (i.p.) injection at 15 mg/kg dose for 6 days. At the end of treatment, mice were sacrificed, tumors were collected and weighted. Tumor growth inhibition (TGI) was calculated as TGI = (Mv –M d)/Mv where Mv is the mean tumor weight of vehicle-treated group and M d is the mean tumor weight of drug-treated group.

For syngeneic cancer studies, the transformed mouse JC mammary adenocarcinoma cells (1 x 10^6, ATCC, Manassas, VA) were implanted subcutaneously in immune-competent BALB/c mice (18–20 g, Charles River, NC). Once the JC xenografts were detectable, mice were then randomly grouped into control or treatment groups (n = 8). K145 was given (20 mg/kg and 35 mg/kg) daily for 15 days. Body weights and volume of tumors were measured every other day, and tumor volume (V) was again calculated. At the end of treatment, mice were sacrificed, tumors were collected and weighted. Tumor samples were homogenized in lysis buffer (50 mM Tris-HCl, 150 mM NaCl, 1 mM EDTA, 1% Triton X100, 0.25% sodium deoxycholate, 0.1% SDS, 1 mM PMSF, pH 7.4) supplemented with protease and phosphatase inhibitor cocktail (Roche) for Western blot analysis.

Acknowledgments

We thank Dr. Sheldon Milstien and Dr. Santiago Lima from the Department of Biochemistry and Molecular Biology, VCU for helpful discussions.
