Conscious attention to the present moment in a receptive way is known as mindfulness. A growing body of research indicates that mindfulness can be taught and cultivated to improve physical and mental health. Accordingly, as part of the coaching competency, mindfulness can be practiced and taught by advanced practice nurses to support lifestyle and behavioral changes, decrease perceived stress, enhance quality of life, and, ultimately, improve health and health outcomes. This article provides an overview of the mechanisms of action, evidence base, and practice of mindfulness, with an emphasis on how to easily incorporate this valuable skill into practice.

Mindfulness

Mindfulness is an ancient concept derived from the Pali word sati, which can be translated as presence of mind. Use of the term mindfulness in this article reflects its roots in Asian Buddhist contemplative practice and its secular health applications as developed by Kabat-Zinn.(Kabat-Zinn, 1994; Kabat-Zinn & University of Massachusetts Medical Center/Worcester. Stress Reduction Clinic., 1990) According to Kabat-Zinn, who popularized the concept in the West, mindfulness involves purposefully paying attention to the present moment in a curious, open way without judgment. Brown and Ryan, (K. W. Brown & Ryan, 2003) experts in the science and application of mindfulness, have described it as receptive attention to and awareness of the present moment. Mindfulness is thought to be more experiential and less analytical than typical wakefulness, providing an opportunity to disengage from habitual and potentially taxing preoccupation in biases, defenses, and rumination.(K. W. Brown, Ryan, & Creswell, 2007) This use of the term mindfulness differs from common use referring to being careful, heedful, or conscientious.

Mindfulness is considered an inherent capacity that can be cultivated through various meditative practices. At a basic level, it involves paying close attention to the present moment, bringing into awareness what is, as well as how one reacts to what is. Ultimately, the practice
involves letting go of judgments (e.g., labeling thoughts/responses as good or bad) to facilitate focusing on any experience that occurs, rather than avoiding some while clinging to others. With practice, most people can cultivate a level of mindfulness that can decrease psychological distress and physical symptomatology.

For example, one can practice being mindful of a particular object or phenomenon, such as one’s breathing, which entails observing the moment-to-moment sensations of each inhalation and exhalation in a receptive, curious manner. When thoughts and emotions arise, they are noticed kindly and simply as thoughts and emotions. One then gently releases them and restores awareness to the object of attention, in this case the breath. Breathing meditation is a common mindfulness practice, especially with novices.

Repeatedly being mindful, through formal practice and/or in daily life, appears to have important effects on mental processes and underlying neural circuitry. (Lutz, Slagter, Dunne, & Davidson, 2008) Research indicates that the mental process mechanisms through which mindfulness enhances physical and mental health include decreased rumination, improved emotional regulation, nonattachment, and less ego-focused thinking. (K. W. Brown & Ryan, 2003; Jain et al., 2007; Sahdra, Shaver, & Brown, 2010; Sanders & Lam, 2010; Shahar, Britton, Sbarra, Figueredo, & Bootzin, 2010) Other mechanisms by which mindfulness affects physical and mental health are an increased sense of coherence, an altered perception of stressors, development of an observing attitude, changes in spirituality, improved attention-related functions, and cognitive flexibility. (Dobkin, 2008; Dobkin & Zhao, 2011; Greeson et al., 2011; Kerr, Josyula, & Littenberg, 2011; Moore & Malinowski, 2009)

Coaching, Advanced Practice, and Mindfulness

According to Spross, (Spross, 2009) coaching is one of six core competencies for advanced practice nurses (APNs). Coaching is an evidence-based, interpersonal process used to engage patients in participating in their own care by building self-care skills. Spross originally conceptualized coaching as a way to ameliorate patients' suffering, and later suggested that it facilitates safe passage for people facing personal transitions. (Spross, 2009) Transitions (e.g., adjusting to living with a chronic illness, providing long-term caregiving) are inherently stressful and can be eased by APNs skilled in coaching. APN coaching can also help patients initiate and
Mindfulness: An Effective Tool

sustain behavior changes that achieve outcomes such as effective self-care, decreased perceived stress, improved quality of life (QOL), and increased self-efficacy.

One of the tools that APN coaches can use to help patients achieve these outcomes is mindfulness. Evidence shows that mindfulness can reduce stress and promote self-care and QoL in a variety of clinical and healthy populations. Another bonus: Mindfulness can be taught and implemented regardless of a patient's race, ethnicity, or socioeconomic status. (Woods-Giscombe & Black, 2010)

**Mindfulness Evidence Base**

**Neurobiology**—Multiple studies using functional magnetic resonance imaging (fMRI) have been done to identify the physiologic processes underlying mindfulness. In several studies, mindfulness has been associated with amygdala deactivation, suggesting a down-regulation of negative emotion. (Chiesa, Brambilla, & Serretti, 2010; Creswell, Way, Eisenberger, & Lieberman, 2007; Modinos, Ormel, & Aleman, 2010; Way, Creswell, Eisenberger, & Lieberman, 2010) Three fMRI studies have suggested another mechanism for the effects of mindfulness, namely, decreased ego-focused thinking. (Kirk Warren Brown, Ryan, Creswell, & Niemiec, 2008; Heppner, 2007; Way et al., 2010) In another fMRI study, a mindful state attenuated perceived emotional intensity when subjects viewed positive, negative, and neutral pictures. (Taylor et al., 2011) This study compared novice and experienced meditators, and found that experienced meditators exhibited deactivation of the medial prefrontal and posterior cingulate cortices, known as the default or baseline mode network, indicating that long-term practice enhances emotional stability by facilitating present-moment awareness and fostering acceptance of various emotional states. Finally, mindfulness has been associated with altered intrinsic functional connectivity, suggesting improved focused attention, sensory processing, and reflective awareness of sensory experiences, as well as increased regional gray matter brain density. (Kilpatrick et al., 2011) (Holzel et al., 2011) More evidence and elaboration of these neurobiologic mechanisms can be found in a review of the neuroscientific research on meditation by Lutz et al. (Lutz et al., 2007)

**Mindfulness-based Stress Reduction (MBSR)**—MBSR, the most written about and studied mindfulness intervention, was developed by Kabat-Zinn (Kabat-Zinn, 1982) as a stress-reduction program to address chronic pain. Early research demonstrated its effectiveness in this regard. (Kabat-Zinn, 1982; Kabat-Zinn, Lipworth, Burney, & Sellers, 1986; Kabat-Zinn,
Lipworth, & Burney, 1985) This highly structured program comprises eight 2.5-hour sessions and a daylong retreat. Components include breath meditation, Hatha yoga postures, body scanning, and discussions related to stress perception and coping. Daily homework includes meditation, yoga, and a variety of “inquiry” exercises to increase one's ability to live more mindfully.

Use of MBSR has been studied in clinical and healthy populations for almost three decades. This technique has been linked to generally improved health in stressed populations,(Grossman, Niemann, Schmidt, & Walach, 2004; Monti et al., 2006) decreased average daily cortisol levels,(Carlson, Speca, Faris, & Patel, 2007) increased immune responsiveness,(Davidson et al., 2003) lower self-reported distress,(Astin et al., 2003; Speca, Carlson, Goodey, & Angen, 2000; Tacon, McComb, Caldera, & Randolph, 2003) and reduced depressive and physical symptoms.(Dobkin & Zhao, 2011) In patients with cancer, MBSR increased meaningfulness, decreased psychological symptoms and fatigue, and improved sleep. A systematic review indicated that MBSR might play a helpful role in cancer care.(Smith, Richardson, Hoffman, & Pilkington, 2005) In a subsequent review of MBSR in breast cancer survivors, Matchim et al(Matchim, Armer, & Stewart, 2011) found that this technique promoted sleep quality and QoL while decreasing stress, distress, state anxiety, and mood disturbances.(Henderson et al., 2012; Lengacher et al., 2012) Physiologic outcomes included improved immune function and blood pressure as well as increased DHEA and cortisol. Because these promising results were based on studies that lacked methodologic rigor, the authors concluded that additional randomized controlled trials with longer follow-up periods were needed.

A systematic review by Fjorback et al(Fjorback, Arendt, Ornbol, Fink, & Walach, 2011) showed evidence supporting the use of MBSR for preventing depression relapse and improving mental health. These authors also cited the need for additional randomized, longitudinal studies. In other clinical populations, evidence suggested that MBSR improved menopausal symptoms, insomnia, anxiety, subjective well-being, empathy, perceived daily stressors, and other mental health indicators, and it decreased pain associated with fibromyalgia and failed back surgery.(K. W. Brown, West, Loverich, & Biegel, 2011; Carmody et al., 2011; Esmer, Blum, Rulf, & Pier, 2010; Gross et al., 2011; Kerrigan et al., 2011; Schmidt et al., 2011; Shapiro, Brown, Thoresen, & Plante, 2011; Vollestad, Sivertsen, & Nielsen, 2011)
A study of healthy individuals showed that MBSR was associated with increases in left-sided anterior activation on electroencephalography, a pattern previously associated with positive affect, and enhanced immune function. (Davidson et al., 2003) Another study supported preliminary effectiveness of a 4-week MBSR program in reducing self-reported stress symptoms among nursing leaders. (Pipe et al., 2009) MBSR has been shown to facilitate the introduction of spirituality and presence into nursing practice in a hospice setting. (Bruce & Davies, 2005) In a literature review, Praissman (Praissman, 2008) found that although additional, well-designed studies are needed, MBSR is safe and effective in decreasing stress in both patients and healthcare providers, and noted that no adverse side effects have been documented.

**Other Mindfulness Meditation-based Approaches**—Several systematic reviews have focused on other types of mindfulness-based interventions. Mars and Abbey (Mars & Abbey, 2010) found that mindfulness meditation (MM) is a valuable intervention, but they cited a need for larger, better-designed studies. MM may provide benefits across the cancer trajectory, from acute to palliative care; additional qualitative research into different styles of MM is recommended. (Shennan, Payne, & Fenlon, 2011) MM-based interventions may improve psychological and physical symptoms associated with chronic pain, but, again, better-designed studies are needed. (Chiesa et al., 2010) Although not conclusive, preliminary evidence suggests that MM-based approaches may be useful in treating eating disorders and preventing substance abuse relapse. (Wanden-Berghe, Sanz-Valero, & Wanden-Berghe, 2011; Zgierska et al., 2009) More recent additions to the literature include two MM-related practices, Loving Kindness and Compassion. A review of these practices showed that they may help manage a variety of mental problems such as depression, social anxiety, marital conflict, anger, coping, and the stress of long-term caregiving. (Hofmann, Grossman, & Hinton, 2011)

**Application in Clinical Practice**

**Meditative Practice**—Meditation is an effective modality for cultivating mindfulness. Meditation derives from the Greek *meditari*, meaning to engage in contemplation or reflection. It has been part of spiritual and healing practices for thousands of years. Meditation is practiced using a variety of techniques to alter how one relates to or suspends the stream of thoughts to relax the body and mind. Most types of meditation have four common elements: (1) a quiet location with as few distractions as possible; (2) assumption of a specific comfortable posture;
(3) a focus of attention (eg, a mantra, an object, the breath); and (4) an open state of mind wherein one lets thoughts and distractions come and go naturally without judging them. MM often uses the breath as the anchor of attention in the present moment, but physical sensations and movements, such as slow walking or yoga postures, are commonly used. As one gains greater skill in MM, a fuller range of experiences, including thoughts and feelings, can be observed as phenomena unfolding from moment to moment without the content of such experiences distracting attention from the present moment. MM is used not just for its potential benefits during the practice period itself; it can also be applied to experiences in daily life.

Although the concept of mindfulness has garnered much attention in psychological, neuroscientific, and health-related research, it is a relatively new tool in advanced nursing practice. Much of the research has been done on MBSR, but the research on MM is generally supportive, which portends greater accessibility of mindfulness-based techniques for both practitioners and patients. Although formal MBSR training may not yet be available or affordable for many who can benefit from it, one can still integrate basic mindfulness techniques into clinical practice. The ability to focus the mind to create an internal state of receptive attention to and awareness of the present moment can be cultivated with routine practice of fairly basic, established techniques. (Kirk Warren Brown et al., 2008; Shapiro et al., 2011) Although many situations such as chronic illness and long-term caregiving are longstanding and seemingly unchangeable, practicing mindfulness can shift one’s perception and relationship with these stressors. APNs can introduce the concept and practice of mindfulness to their clinical practice by using the information, suggestions, and resources in Table 1, Table 2, and Table 3. In addition, O’Haver Day and Horton-Deutsch (O’Haver Day & Horton-Deutsch, 2004a, 2004b) provide a description and review of empirical support for mindfulness-based interventions, including a useful case study integrating MM in advanced practice psychiatric nursing.

**Anticipatory Guidance**—The literature on mindfulness provides important insights that may facilitate the acquisition of this potentially beneficial skill. At first, some people may experience resistance to or difficulty with the practice. In one qualitative study, participants described moments of distress related to MBSR practice. (Kerr et al., 2011) However, they also reported being able to develop a “witnessing attitude” toward their distress. Learning to be present and aware involves behavior change, but it is possible and accessible for everyone. Although people tend to resist change, even when they know it will benefit them, an acceptance
of initial feelings of discomfort can facilitate behavior change. (Maxwell, 1995) Merely explaining this phenomenon to patients may help them feel less self-critical as they learn new health behaviors.

Learning to be more mindful is a process. An ancient proverb teaches that “the mind belongs to you; you do not belong to the mind.” Training the mind is akin to training the body. To increase physical strength and stamina, one starts a program slowly and then gradually increases the duration and intensity of training over time. In general, one does not begin increasing strength and stamina by lifting 100 pounds and running 10 miles. These concepts also pertain to the training of the mind. It is a process. One can begin simply by learning to become aware of the breath.

The practice of meditation can enhance the ability to be mindful. Becoming more mindful can begin by simply sitting 5 minutes each day, quietly focused on the breath. Although breath is frequently used as a tool for focusing the mind, a candle flame, a meaningful word, or gazing at a beautiful piece of art or something in nature works as well. Broadbent (Broadbent, 2007) stated that mindfulness in action is a process of learning and growing that can begin with immersing oneself in a favorite activity, remaining aware and open to the thoughts that arise, and that, over time, feelings of fear and anxiety are more easily released. With continued practice, one learns to be more observant and aware in all aspects of life, without the need for habitual judging, labeling, and reacting. (Lutz et al., 2007)

**Conclusion**

An abundance of research on MBSR and a growing body of research on other MM techniques are available, providing initial support for benefits. Additional well-designed longitudinal studies are needed in healthy and vulnerable populations, with a focus on underlying mechanisms of mindfulness, as well as on the effectiveness of various mindfulness-based meditation strategies. Clinical effectiveness research and less formal evidence from practice can provide feedback to profoundly inform future research. In the interim, APNs can reasonably integrate mindfulness-based techniques into clinical practice, given the potential benefits and the relative ease with which it can be done.

In a research update on mindfulness, Greeson\textsuperscript{17} concluded that mindfulness enhances health and well-being by increasing attention, awareness, and acceptance of thoughts and
emotions, which increases adaptation to stressors. Practicing mindfulness may lead to major improvements in multiple patient outcomes. Finally, in addition to potentially decreasing perceived stress, mindfulness practice may foster self-reflection, thereby enhancing NPs’ coaching abilities.

1. Start where you are; 5-10 minutes of daily practice can cultivate mindful
Mindfulness: An Effective Tool

awareness. A reasonable goal is 15-20 minutes most days of the week.

2. Choose a specific time each day. Developing a “discipline” is often most successful if practice is done in the morning before the day gets busy.

3. If you miss your morning practice, practice when you can during the day.

4. Acknowledge that learning new behaviors is difficult and reward yourself for your willingness to try and let go of criticizing yourself.

5. Choose a meditation activity that works for you and use a variety depending on what you need: Focus on breathing while seated, lying down or walking; progress to tai chi or yoga if you wish.

---

TABLE 2. Easy Ways to be Mindful*

1. Do one task at a time. Multi-tasking is inefficient and stressful.

2. Engage in walking meditation by leaving your phone and focusing on the walking and what is around you.

3. Eat a meal silently, away from the television or computer.

4. Take 3 deep breaths when you awaken and just before sleep.

5. Take a deep breath when you feel yourself getting tense.

6. Schedule play time.

7. Laugh just because you can. Try laughing in your car at stoplights; no one knows you are not using a device they cannot see.

8. Pay attention to what your body tells you; rest a bit when you are tired and stretch when you are tense.

9. Practice gratitude each day.

10. Receive help when it is offered.
